ACKNOWLEDGEMENTS

The regional staff of Environmental Protection carried out most of the monitoring, either directly or by using co-op students and contractors. Zenon Environmental Inc. analyzed the samples except those for mercury which were analyzed by Analytical Service Laboratories Ltd. Information was also obtained from industries, from Environmental Protection, from the Canada-B.C. Water Quality Monitoring Agreement, from regional offices of the Ministry of Health, from the federal departments of Environment and of Fisheries and Oceans, from B.C. Hydro, and from the Greater Vancouver Regional District.

1. SUMMARY

The task of setting water quality objectives in priority basins in British Columbia began in mid 1982. By the end of 1991, the Ministry had set water quality objectives in 34 bodies of water throughout the Province. Monitoring to check the attainment of objectives started, on an annual basis, in 1987. This report presents the results of monitoring done in 1991 to check the attainment of objectives in certain selected basins.

The results are summarized in a series of tables. Overall, the objectives were met about 90 percent of the time, an outcome similar to those of 1988 to 1990. Although this result falls short of an ideal 100 percent compliance, it generally applies only to objectives that were set in problem areas. Thus, while the monitoring results describe indirectly how well problems are being dealt with, they do not describe the state of water quality in the Province as a whole. Variables for which objectives were sometimes exceeded in more than one basin included the following: fecal coliforms, E. coli, enterococci, suspended solids, turbidity, phosphorus, chlorophyll-a, pH, dissolved oxygen, temperature, cyanide, copper in water and sediments, iron, lead in water and sediments, mercury, zinc in sediments, and PCBs in sediments.

Cases of objectives being exceeded need investigation to determine the cause and the possible need for corrective action. Monitoring in future years will indicate whether problems are persisting or being solved. Monitoring also shows how close water quality conditions are to ideal and results are thus one measure of the state of the environment in B.C.

2. INTRODUCTION

In 1981, the Auditor General recommended that the Ministry develop a method of measuring its performance in safeguarding water quality. To fulfill this recommendation, the Ministry undertook to set water quality objectives for fresh and marine surface waters of British Columbia.

Water quality objectives are safe conditions or levels of contaminants which will protect the most sensitive water use of a specific body of water. They establish a reference against which the state of water quality at a specific site can be checked, as recommended by the Auditor General. They can also be used to prepare Waste Management Permits or Plans and to measure their effectiveness. They are thus a basic tool for use in maintaining a healthy aquatic environment.

Work on water quality objectives began in 1982. By the beginning of 1992, objectives had been set in 34 separate bodies of water and updated in one. In each basin considered, some type of water quality problem was expected due to human activity. Objectives have been set for lakes, rivers, creeks, and marine areas and cover all six Environmental Regions of the Province.

This report for 1991 is the sixth in a series of annual reports which began in 1986. Since 1987, funds have been allocated for the minimum ambient monitoring needed to check the attainment of the objectives. As a result, a picture of how well objectives are met was obtained from 1987 to 1990 and is again given here for 1991. The report is for the use of the managers of the water resource. It shows where conditions are acceptable and where further evaluation is needed to solve water quality problems. It can also be used by anyone interested in the present state of water quality in a given basin although, to keep this report to a

reasonable length, familiarity with the background reports on water quality objectives for each basin is assumed. Copies of the background reports on objectives can be obtained from the Water Quality Branch of the Ministry in Victoria.

The water basins in which water quality objectives are set are usually chosen because of perceived water quality problems. Thus, results presented here indicate conditions in likely problem areas, but do not reflect the state of water quality in the Province as a whole. There are many bodies of water where water quality is relatively unaffected by humans and likely to remain so for the foreseeable future. Nevertheless, reports in this series are one measure of the state of the environment regarding water quality in British Columbia.

3. METHODS OF PRESENTING AND INTERPRETING THE DATA

3.1 Reports on Objectives

By the end of 1991, the Ministry of Environment had completed 34 reports on water quality objectives for specific water basins. The complexity and size of the reports varied considerably, depending upon the basin considered. These water basins were distributed among the Environment Regions as follows:

Vancouver Island	4
Skeena	4
Northern Interior	8
Southern Interior	9
Kootenay	3
Lower Mainland	6
	—
Total	34

Work is in progress on another 16 reports for different water basins. These reports are now at various stages of completion.

3.2 Tables of Results

Data collected in 1991 to check objectives are summarized in Tables 2 to 28, with a separate table for each of the 27 water basins monitored. Seven basins were not monitored in 1991, due either to low priority or late completion of the objectives during 1991. Decisions on which basins to monitor and on the details of monitoring and funding were reached early in the year after close consultation with the Regions. The work to be done was described in monitoring schedules and the progress of the work was followed during the year.

Each table lists all the objectives that have been set, as they appear in the summary table of each objectives reports. A few of the objectives have been updated to reflect new water quality criteria and procedures. For example, we are now using chlorophyll-a instead of periphyton biomass and total ammonia-N instead of un-ionized ammonia-N. The 90th percentile of 400 MPN/100 mL for fecal coliforms is used when high fecal coliform values are recorded at bathing beaches.

The tables summarize the measurements made to check the objectives. These include sites, sampling dates, number of samples taken, and the values obtained. For each objective checked, the sites and tributaries are listed in the tables in an upstream to downstream sequence, starting with the upstream site or tributary. Finally, a concluding statement about the results is given.

Five different concluding statements are used: objective met, objective not met, indefinite result, objective not checked, and omitted 1991. The result is reported as indefinite if there were insufficient data to check the objective, or the data were suspect, or the minimum detectable concentration was too high. The objective is reported as not checked if, for some reason, planned data collection did not take place. The objective is reported as omitted if there was a deliberate plan to not monitor because of low priority, taking into account past results. We consider these tables to be the most important part of this report since they show where and when objectives were met in 1991.

3.3 Text

The text in this report first gives a provincial overview of the results. The tabulated data for each body of water are then described briefly, by Region, mentioning the highlights and drawing some general conclusions. Qualifying statements such as: "...the objectives were nearly met, slightly exceeded or probably met..."

are avoided as being too speculative without the support of further evidence to explain them. Thus, objectives exceeded by a wide margin are categorized equally with apparent borderline cases. While a more detailed interpretation is desirable, the presentation of data that would be required to document the significance of results in more detail is beyond the scope of a province-wide report.

There is also no attempt to explain what may have caused the results or to comment on the effect of objectives not being met. Such assessments would entail consideration of river flows, effluent discharges, whether objectives are long-term or short-term, the degree to which objectives are exceeded, quality assurance, and other factors. In the past, assessments of this type were left to Regions to carry out on an ongoing basis. In the future, we may present information collected over a period of time in short state-of-environment type of reports for specific basins. A quality assurance program to test the accuracy and precision of laboratory data was introduced in 1991 and the results are presented in the following chapter 4.

The report is written to guide those involved in managing water quality by focusing on areas of concern where further assessment or inspection may be needed. Since monitoring to check water quality objectives covers only a short time span, usually at most 30 days, we believe that any instance when objectives were not met could be significant and is worth a more detailed look. Further study could show that certain objectives were exceeded due to natural phenomena. On the other hand, it could reveal the need for corrective action if there were human causes to the problem.

3.4 Figures

The 34 basins where objectives have been set are shown on a location map in Figure 1. The 27 water basins monitored in 1991

are detailed in separate maps, Figures 2 to 28, on which sampling sites referred to in the tables are shown. Each figure number corresponds to the table of the same number.

3.5 Guide to Ranking Future Monitoring

Due to limited funds, we cannot monitor all basins where objectives have been set each year. Monitoring is therefore ranked as follows:

1st priority: any basin with less than three years of complete monitoring and any basin considered provincially or internationally significant. Examples of significant basins are the Fraser River due to fisheries, the Okanagan Valley lakes due to recreation, the lower Columbia River due to transboundary effects, and Burrard Inlet due to a federal-provincial plan.

2nd priority: any basin in which, after at least three years monitoring, a number of objectives are not regularly attained and there is either a local expression of concern or a plan for short-term action.

3rd priority: any basin as for the 2nd priority above, but where the concern and the plan of action are undefined.

4th priority: any basin in which, after at least three years monitoring, most objectives are either being met or the corrective plan of action is long term.

4. QUALITY ASSURANCE PROGRAM

4.1 Introduction

A quality assurance program, describing the accuracy and precision of test results, was begun in 1991. The program was limited in scope due both to scarce resources and the fact that it was the first of its type to be undertaken. Details on procedures and results are in a separate Water Quality Branch report issued in April, 1992.

Eight variables were chosen for testing in the program. These were mercury, total copper, total iron, total lead, total zinc, cyanide, ammonia nitrogen, and nitrite nitrogen. These were chosen on the basis of important objectives most frequently exceeded. Fecal coliforms was not included due to the lack of standard references.

In an ideal situation one would aim to measure the accuracy and precision of the total monitoring process. This would include sample collection, handling in the field, shipping, storage, and laboratory analysis. Only the accuracy and precision of the laboratory analyses were measured in the 1991 program (except for mercury) and, strictly speaking, the results apply to just a short operating period of the laboratory, not year-round operation.

4.2 Procedure

Standard reference solutions were prepared by a commercial laboratory using clean-room techniques. The concentrations chosen for these solutions were close to the maximum criterion level to protect aquatic life for each substance. Results would thus indicate the confidence one may have in laboratory data at levels where sensitive objectives may be exceeded.

For mercury, a reference solution containing 90 ng/L Hg was prepared. The procedure used for mercury differed from that used for the other substances because the literature indicates that, due to contamination problems, clean-room techniques are essential to ensure reliable analytical results. The reference solution was therefore sent to three laboratories for comparative testing. The laboratory with the best results being ASL (Analytical Service Laboratories Ltd.) of Vancouver, it was subsequently chosen to perform all 1991 mercury analyses to check objectives.

In measuring mercury, travel blanks were used to monitor the effect that sampling in the field might have on sample contamination. Travel blanks are sample bottles containing pre-acidified, mercury-free distilled water. These are opened in the field, subjected to the same handling as normal sample bottles (except they are not filled with sample or preservative), capped and sent to the laboratory for mercury analysis along with the true samples. Any mercury found in the travel blanks, together with a knowledge of laboratory accuracy, gives a measure of contamination from the field.

For the other metals, a reference solution containing copper, iron, lead, and zinc was prepared at the following nominal concentrations: 5 ug/L Cu, 300 ug/L Fe, 10 ug/L Pb, and 50 ug/L Zn. The precise concentrations were determined by the National Research Council of Canada laboratory in Ottawa. A total of 25 samples of this solution were sent to Zenon Environmental Inc. of Vancouver, which is the laboratory generally used for objectives work. These samples were sent blind, that is to say the laboratory was not aware that they were reference samples.

Separate reference solutions were prepared for cyanide, ammonia nitrogen, and nitrite nitrogen, at the following nominal concentrations: 0.200 mg/L CN measured as strong-acid dissociable cyanide (similar to total cyanide), 10 mg/L NH₃-N, and 0.060 mg/L

NO2-N. The precise concentrations were determined by CB Research International laboratory in Victoria. Twenty four samples of each of these reference solutions were sent to Zenon, again as blind samples.

4.3 Results

The results are given in terms of the accuracy and the precision of the laboratory measurements. The accuracy is a measure of how the analytical result differs from the true value. It is expressed as a percent by dividing the analytical result by the true concentration of the reference solution. The precision is a measure of the repeatability of the analysis. It is also expressed as a percent by dividing the standard deviation of the analytical results by their mean.

a) mercury

ASL achieved an accuracy of 100 - 104% and a precision of 2%. This means that mercury results, at the 90 ng/L level, are expected to be within 4% of the true value and can be replicated within 2% as far as laboratory measurements are concerned.

The problem of mercury contamination in the field during sampling was partly addressed by the results from travel blanks. Field data were received from the lower Fraser area, the lower Columbia River, Howe Sound, and Burrard Inlet. Out of 25 travel blanks, 5 showed the presence of mercury. All 5 were from Burrard Inlet and gave an average mercury level of 11 ng/L. These results indicate that, in Burrard Inlet, mercury contamination may account for about 50% of the average water quality objective but for less than 1% of the maximum objective.

b) copper

Zenon gave an average accuracy of 210% and a precision of 12% at the 5 ug/L level. Copper results are therefore expected to be

about 110% higher than the true value and can be replicated within 12% by the laboratory. A possible outlier was noted in the data set which, when eliminated, gave an average accuracy of 146%. In this case, confidence in the results is improved to an expected 46% above the true value.

c) iron

The Zenon accuracy averaged 100% and the precision 14% at the 300 ug/L level. Iron results are therefore expected to be equal to the true value, on average, and can be replicated within 14% in the laboratory. However, while the average accuracy was high the range varied between 73% and 112%.

d) lead

The Zenon accuracy averaged 129% and the precision 11% at the 10 ug/L level. Lead results are therefore likely to be 29% higher than the true value and can be replicated within 11%.

e) zinc

The Zenon accuracy averaged 85% and the precision 5% at the 50 ug/L level. Thus zinc results are expected to be 15% below the true value and can be replicated within 5% in the laboratory. Excluding outliers, the accuracy becomes 122% and results would likely be 22% above the true value.

f) cyanide (strong-acid dissociable)

On average the Zenon accuracy was 82% and the precision was 38% at the 0.200 mg/L level. This means that cyanide measurements are expected to be 18% below the true value and can be replicated within 38%. These relatively poor results may have been due to deterioration of the reference samples during storage before analysis, although this possibility will need to be verified.

g) ammonia nitrogen

Zenon accuracy averaged 106% and the precision was 11% at the 10 mg/L level. This means that ammonia nitrogen analyses will average 6% higher than the true value and can be replicated within 11%.

h) nitrite nitrogen

Zenon accuracy averaged 121% and the precision was 6% at the 0.060 mg/L level. The accuracy was poor considering that the target value (0.060 mg/L) was well above the detection limit. The result indicates that nitrite nitrogen analyses will average 21% higher than the true value. Analytical replication would be within 6% which is considered to be a good degree of precision.

5. PROVINCIAL OVERVIEW OF RESULTS

5.1 Presentation of Results

In the tables summarizing the monitoring data, there are five kinds of concluding statement. These are: objective met, objective not met, objective not checked, objective omitted, and indefinite result.

To get an overview of performance for the Province, the number of occurrences of each conclusion were totalled for each water basin from the summary tables. In compiling these totals, each instance of a maximum (or minimum) objective being met or not met was counted together with all average and percentile values.

The results of this compilation are shown in Table 1. The sum of occurrences for each kind of conclusion is given by Region and then totalled for the whole Province. The occurrences are also expressed as a percent of the total of all occurrences, both by Region and for the Province as a whole.

5.2 Discussion of Results

Although the results apply to specific occurrences, we will assume in this analysis that they are representative of the whole year. This simplification is a conservative approach to describing the state of water quality since data were usually collected during worst case conditions.

Table 1 shows that the objectives were met 78% of the time in the Province as a whole in 1991. This result varied according to Region from 63% to 88%. Objectives were not met from between 0% to 17% of the time, with an overall average of 9%.

The occurrence of objectives not checked, objectives omitted, or indefinite results averaged 3%, 6%, and 4%, respectively. If we subtract these relatively minor instances of no result from the total, then the number of instances (or percent of time) that objectives were met becomes 90% and the number not met 10%.

We can therefore state that in the Province as a whole the objectives were met about 90% of the time in 1991. This is an approximate statement since it can be influenced by several monitoring factors. For example, the frequency at which particular objectives in any Region are monitored can change the final result. The inclusion or omission of water basins with either serious or minor water quality problems will obviously also affect the outcome.

The overall result for 1991 was a shade lower than results for previous years (1987 to 1990). As the monitoring program is repeated in future years the general picture could change even further. New basins will be added and, with a fixed monitoring budget, there will be a tendency to cease monitoring in areas where objectives are being met consistently by a wide margin (as described in section 3.5). As a first priority, we will probably concentrate on areas where the worst man-made water quality problems occur. This strategy could, at first, produce a more negative general result. We would expect the situation to improve in subsequent years as corrective action is taken. The goal, of course, is for water quality objectives to be met 100% of the time in all such areas. Monitoring in future years, followed by corrective action where required, will show how close we can get to this ideal situation.

6. VANCOUVER ISLAND REGION

6.1 Cowichan-Koksilah Rivers

Data and site locations are presented in Table 2 and Figure 2, respectively.

The Cowichan River is the most important river on Vancouver Island for recreational and commercial fisheries. The Koksilah River is a major tributary of the Cowichan River near its mouth. Data were collected only on the Cowichan River in 1991.

The objective for fecal coliforms was not met in the Cowichan River towards the mouth, as has been the case since monitoring started in 1989. This objective is fairly restrictive since it was set to protect drinking-water use after disinfection only. Monitoring for other microbiological indicators and in other parts of the basin was not carried out in 1991. As recommended in the 1989 report, the sources of possible bacteriological contamination need to be established before the situation can be corrected.

Dissolved oxygen levels, measured in early summer, met the objective in the Cowichan River. In 1989 and 1990, values measured in late summer were at times below objective levels in both rivers, especially in the lower reaches.

The objectives for turbidity, suspended solids, and ammonia were generally met throughout the Cowichan River as has usually been the case in the past. No data were collected on chlorophyll-a, copper, lead, zinc, and copper-8 quinolinolate. While the objectives for heavy metals have been met in the past, those for chlorophyll-a and copper-8 have never been checked.

6.2 Middle Quinsam Lake

Data and site locations are presented in Table 3 and Figure 3, respectively.

Middle Quinsam Lake drains via the Quinsam River into the Campbell River near its estuary. The Middle Quinsam Lake sub-basin is a valuable habitat for trout and salmon and could be impacted by an open-pit coal mine now being developed in the area.

Not all the objectives needed to be checked in 1991 because the mine was operating at about 50 percent of full-scale capacity and there was no mining in the Long Lake area. Thus some measurements were deliberately omitted, as shown in Table 3.

Most of the objectives tested were met. The only exceptions were results for cadmium, cobalt, and lead which were indefinite due to high detection limits. Objectives met included those for phosphorus in Long and Middle Quinsam lakes, suspended solids, ammonia, nitrate, nitrite, dissolved oxygen, aluminum, arsenic, copper, iron, manganese, mercury, nickel, silver, and zinc. The results for pH were indefinite because insufficient samples were collected in 30 days to calculate medians and 90th percentiles. All these results were similar to those obtained in 1989 and 1990, except for the zinc objective which was exceeded in 1990.

6.3 Oyster River

Data and site locations are presented in Table 4 and Figure 4, respectively.

The Oyster River flows from the Forbidden Plateau area into the Strait of Georgia, south of Campbell River. The river and its tributaries are important habitat for several species of trout and salmon. The main threats to water quality are logging and mine

exploration. The latter is expected to lead to active mining in the future, especially for coal.

Most of the objectives were checked in 1991 in contrast to 1990, the first year of monitoring, when many measurements were omitted. The only objective exceeded was for chromium in the Oyster River upstream from Adrian Creek near the headwaters. Since all other chromium values were indefinite due to high detection limits, further testing is recommended. Objectives met included those for turbidity, suspended solids, ammonia, nitrite, nitrate, pH, aluminum, arsenic, cobalt, lead, manganese, nickel, and zinc. The results for cadmium, copper, and iron were indefinite because the detection limits were too high and there were insufficient data to confirm the coliform objective. Overall, the results mirrored those obtained in 1990.

7. SKEENA REGION

7.1 Bulkley River

Data and site locations are presented in Table 5 and Figure 5, respectively.

The Bulkley River is a major tributary to the Skeena River. It is an important river for fisheries and has some drinking water use. The main influences on water quality are treated municipal effluent from Houston and Smithers and possible contamination in the headwaters from mining.

The objective for fecal coliforms was not met upstream from Houston although it was met upstream from Smithers. The objective is fairly restrictive in these locations since it was set to protect drinking water use. Elsewhere, the objective was met as were all other objectives checked. These included objectives for turbidity, suspended solids, ammonia, nitrite, and dissolved oxygen. Similar results have been obtained from 1987 to 1990. The source of the relatively higher fecal coliform counts upstream from Houston needs to be established if the problem is to be corrected.

7.2 Kathlyn Seymour, Round, and Tyhee Lakes

Data and site locations are presented in Table 6 and Figure 6, respectively.

These four small lakes, in the Smithers area, are used for recreation, domestic water supply, and irrigation.

The fecal coliform objectives were met at all domestic water intakes and beaches where measured in all four lakes. Water at intakes in Kathlyn, Seymour, and Tyhee lakes have occasionally

exceeded the objective in the past (1988-1990). The objectives for turbidity and colour were exceeded at times in all the lakes except Tyhee Lake.

The total phosphorus objective was exceeded in Kathlyn Lake but could not be checked in Round Lake because stratification had occurred at sampling time. The objective was not checked in Tyhee Lake. All the objective results reflect the tendency for the lakes to be eutrophic. Long-term measures outlined in the assessment report setting the objectives need to be implemented to reverse this trend.

7.3 Lower Kitimat River and Arm

The river and arm are an important migration route for salmonids, and the water is also used for recreation and for industrial and municipal supplies. A kraft pulp mill and an aluminum smelter are located in the water basin.

The objectives were monitored for three years from 1988 to 1990. The data obtained were fairly consistent and most objectives were met, except at times those for cyanide and certain metals. No monitoring was carried out in 1991 and an assessment to update the existing objectives was started in 1992.

7.4 Lakelse Lake

Data and site locations are presented in Table 7 and Figure 7, respectively.

Lakelse Lake drains into the Skeena River and is important for salmon spawning and rearing and for recreation. It is also used as a domestic water supply.

All the objectives checked were met in 1991, except that for

chlorophyll-a which was exceeded. The fecal coliform objective was indefinite due to insufficient samples. Objectives met included those for turbidity, phosphorus, and dissolved oxygen. Similar results were obtained from 1987 to 1990, when all objectives were met (except chlorophyll-a in 1990), and indicate that the lake is in good condition.

8. NORTHERN INTERIOR REGION

8.1 Charlie Lake

Data and site locations are presented in Table 8 and Figure 8, respectively.

Charlie Lake is used as a drinking water supply and for recreation. Agriculture and development around the lake are factors affecting water quality.

At the Charlie Lake Park bathing beach, the geometric mean and 90th percentile fecal coliform objectives were met. As in 1989 and 1990, there were no beach closures. At the Fort St. John intake, the more stringent fecal coliform objective to protect drinking water was met from January to May but was exceeded from May to November. In the past, this objective has sometimes been met (1987, 1988, 1990) and sometimes been exceeded (1989).

The phosphorus objective at spring overturn was met for the first time since 1987. The objective for other times of the year was usually met until late July after which time it was exceeded. These results show that the lake was not as eutrophic in 1991 as it has been in the past.

8.2 Bullmoose Creek

Data and site locations are presented in Table 9 and Figure 9, respectively.

Bullmoose Creek and its tributaries (West and South Bullmoose Creek) are important recreational fish habitat. The creeks are adjacent to an open pit coal mine.

The objectives for turbidity and suspended solids were not

checked in 1991. In the past, these objectives have sometimes been exceeded during the freshet period. The objective for chlorophyll-a, which was often exceeded in 1989, was met at all sites checked in 1991. Measurements for substrate sedimentation were indefinite due to use of improper particle size.

No other objectives were checked in 1991 although they have usually been met in past years. They included those for fecal coliforms, ammonia, nitrite, nitrate, dissolved oxygen, and pH.

8.3 Nechako River

Data and site locations are presented in Table 10 and Figure 10, respectively.

The Nechako River, a major tributary to the Fraser River at Prince George, has its flow controlled for power generation. The river is an important route for migrating salmon.

The fecal coliform objective was met in the Nechako River at all sites checked in 1991. Such a result has not been obtained since 1987. In major tributaries (Stuart River, Necoslie River, and Chilako River), the objective was either not checked or the results were indefinite due to insufficient sampling. The objective has been met in these tributaries in the past.

Other objectives which were met in the Nechako River (and the Stuart River as applicable) were those for ammonia, nitrite, dissolved oxygen, and pH. Total gas pressure was not measured although the objective was met in 1989 and 1990. Chlorophyll-a was also omitted. In 1988, the only year it was checked, the objective was met in the Nechako River but exceeded in the Stuart River. No measurements were made in the Chilako River in 1991.

The temperature objective at a site downstream from Cheslatta

Falls was met during the winter months, from January to June and after late September. However, during the summer months (June to September) the objective was frequently exceeded. Similar results have been obtained since 1987. Further downstream, just below Vanderhoof, a less stringent temperature objective was met all year except for the last week in June.

8.4 Pine River

The Pine River, a tributary to the Peace River, supplies water to Chetwynd and supports significant sportfish populations.

The objectives were monitored for four years from 1987 to 1990. The results showed that objectives were being met fairly consistently. No monitoring was carried out in 1991 and the priority for future monitoring is low at this time.

8.5 Pouce Coupe River and Dawson Creek

The Pouce Coupe River runs into the Peace River inside the Alberta Border. Dawson Creek is its major tributary. The waters are affected mainly by municipal discharges.

The objectives were checked for four years, from 1987 to 1990, although complete data were not obtained in any one year. In the Pouce Coupr River, the fecal coliform objective was met but most other objectives (nutrients, turbidity) were exceeded at one time or another. In Dawson Creek, fecal coliform objectives do not apply but most of the other objectives were also exceeded on several occasions.

No monitoring was carried out in 1991. The municipal treatment plants need to be upgraded if the objectives are to be met.

8.6 Peace River

Data and site locations are presented in Table 11 and Figure 11, respectively.

Objectives have been set for the Peace River between the Bennett Dam and the B.C.-Alberta Border. The water is important for aquatic life and irrigation and can be affected by municipal discharges, an oil and gas refinery, and a pulp mill built in 1988 after the objectives were set. The objectives were first checked in 1988.

Objectives in the Peace River were checked for three years from 1988 to 1990 and thus only partial testing was carried out in 1991. Among the objectives omitted or not checked in 1991 but exceeded at times in the past were fecal coliforms, suspended solids, turbidity, copper, and chromium. Other objectives which have been met in the past but were also not checked in 1991 included fluoride, cyanide, ammonia, total dissolved gases, phenol, chlorophenols, lead, nickel, and zinc.

Those objectives measured in 1991 were all met. They included dissolved oxygen, pH, temperature, and nickel. Considering the importance of the Peace River, both in B.C. and in Alberta, we recommend that all objectives be checked regularly in the future as monitoring funds permit.

8.7 Williams Lake

Data and site locations are presented in Table 12 and Figure 12, respectively.

Williams Lake drains to the Fraser River and is important for drinking water, recreation, and aquatic life. The water quality is affected by nutrients from traditional farming practices in the San

Jose River drainage, the main inlet to the lake.

Monitoring to check objectives has been carried since 1987. The objective for fecal coliforms to protect bathing beaches was met in 1991 as it has been in the past. The objective to protect drinking water was not checked. It was met in 1989, the only year it was measured.

The objective for turbidity was met but the objectives for phosphorus, chlorophyll-a, dissolved oxygen, and water clarity were all exceeded. These results were similar to those obtained in the past and reflect the current eutrophic state of the lake.

8.8 Upper Finlay River

The Finlay River, located in the north east part of the Province, drains into the north end of Williston Lake. The area of the upper Finlay was the site of a gold and silver mine and mill, now closed. Objectives apply to Jock and Galen creeks which eventually flow into the upper Finlay River.

The objectives were checked in 1987. Since the area is remote and the operation is closed, no further monitoring has been carried out since. Future monitoring may be needed if the mill is reactivated on a full-time basis.

9. SOUTHERN INTERIOR REGION

9.1 Bonaparte River

Data and site locations are presented in Table 13 and Figure 13, respectively.

The Bonaparte River is a tributary to the Thompson River. It is an important trout habitat and is affected by cattle farming and municipal discharges. Its main tributaries are Clinton Creek and Loon Creek.

The objectives have been monitored since 1987 with varying degrees of completion. As a result, only limited monitoring was carried out in 1991. Objectives which have been exceeded consistently at times include suspended solids, turbidity, and chlorophyll-a. The fecal coliform objective was usually met in the upper reaches but exceeded near the mouth. Objectives which are usually met include those for ammonia, nitrite, pH, and dissolved oxygen. In Loon Lake, the dissolved oxygen objective was not met in 1991, duplicating past results.

The water quality situation in the Bonaparte River basin seems to be fairly stable and well defined. Unless there are new developments or changes, future monitoring to check objectives will be a low priority at this time.

9.2 Okanagan Valley Lakes

Data and site locations are presented in Table 14 and Figure 14, respectively.

To date, objectives have only been set in the five main lakes for phosphorus, which is the main factor controlling the trophic

state of the lakes. The lakes are highly valued for recreation, fisheries, and as a source of drinking and irrigation water.

The short-term phosphorus objective was met in Wood Lake, as it was in 1990. This new trend is a change from previous results obtained in 1987, 1988, and 1989 when the objective was not met. The phosphorus objectives for Kalamalka and Okanagan lakes were met, including in the Vernon Arm of Okanagan Lake where the objective had been exceeded in previous years until 1990. The objective was also met in Skaha Lake for the first time since 1987, but was exceeded in Osoyoos Lake as it has been in the past.

9.3 Similkameen River

Data and site locations are presented in Table 15 and Figure 15, respectively.

The Similkameen River flows from Manning Park, through the south Okanagan, then south across the U.S. border. It is important for fisheries, drinking water, and irrigation. Water quality can be affected by mining and municipal discharges. The water quality objectives were updated in 1990 because of an increase in mining activity in the Hedley Creek area.

Objectives were not checked in the Similkameen River from Manning Park to Princeton, in Allison Creek, and in Wolfe Creek in either 1990 or 1991. Taking into account past results, these areas were considered a low priority for monitoring.

Fewer objectives were checked in the Similkameen River in 1991 and none were checked in Hedley Creek. Objectives met included those for cyanide (weak-acid dissociable), arsenic, ammonia, pH, chromium, copper, iron, lead, manganese, molybdenum, nickel, and zinc. Objectives for iron and zinc had been exceeded in 1990. The fecal coliform objective, set to protect the water

for drinking after disinfection only, was not met at times in the Similkameen River. A similar result was obtained in 1989 and 1990.

Since there are less than three years of complete monitoring to check the updated objectives, future monitoring of these objectives should be a high priority.

9.4 Cahill Creek

Data and site locations are presented in Table 16 and Figure 16, respectively.

Cahill Creek, its tributaries (Nickel Plate Mine Creek and Sunset Creek), and a parallel stream (Red Top Gulch Creek) enter the Similkameen River near Hedley. This watershed is the site of a gold mine and mill which began operating in 1987. Monitoring to check objectives began the same year.

The objectives-checking program was scaled down in 1991 in the same way as in 1990. Whereas most of the objectives had been met in 1990 as they had been in previous years, there were some instances of objectives being exceeded in 1991. These included objectives for suspended solids, turbidity, dissolved solids, sulphate, cyanide in various forms (cyanide, in the weak-acid dissociable form, was not met in 1988 and 1989 at Cahill Creek at the mouth), nitrate, pH, and zinc. The objectives that were met at all times in 1991 included those for nitrite, aluminum, cadmium, and molybdenum. Due to the relatively large number of objectives that were exceeded in 1991, future monitoring should be a fairly high priority.

9.5 Bessette Creek

Data and site locations are presented in Table 17 and Figure 17, respectively.

Bessette Creek, which flows into the Shuswap River, is formed by the joining of Harris and Duteau creeks near the town of Lumby. Lawson Creek, and its tributary Spider Creek, flow into Duteau Creek. These creeks provide spawning habitat for trout and four species of salmon. Activities that can affect water quality include a telephone pole treatment plant near Harris Creek, a woodwaste landfill along Duteau Creek, and agricultural operations generally.

While partial monitoring was carried out last year, 1991 is the first year most of the objectives were checked. Fecal coliform, E. coli, and enterococci objectives to protect the water for drinking after partial treatment were generally not met in Bessette, Lawson, and Spider creeks. Other objectives exceeded at times were suspended solids and turbidity in Lawson Creek, pH in Spider Creek, and dissolved oxygen in Lawson and Spider creeks.

Objectives that were met included those for suspended solids and turbidity in Bessette and Spider creeks, ammonia, nitrite, and nitrate in all creeks, colour in Lawson and Spider creeks, temperature in Duteau Creek, pH in Bessette, Lawson, and Harris creeks, dissolved oxygen in Bessette and Harris creeks, and resin acids in Lawson and Spider creeks.

In Harris Creek, the important chlorophenol objectives were met in the sediments. In the water column, mono and dichlorophenol could not be analysed by the laboratory, tri and pentachlorophenol were below detection limits, and tetrachlorophenol met the objective.

Continued monitoring to check objectives will be a high priority in this basin for the next few years.

9.6 Tributaries to Okanagan Lake near Westbank

Data and site locations are presented in Table 18 and Figure 18, respectively.

Objectives were set for Peachland, Trepanier, and Westbank creeks which flow into Okanagan Lake in the Peachland-Westbank area. Peachland and Trepanier creeks support spawning populations of kokanee or trout, and all three creeks are used for irrigation and domestic water supplies. Peachland and Trepanier creeks can be affected by seepage from a molybdenum mine which closed recently. Treated sewage effluent is discharged to Westbank Creek.

While partial monitoring was carried out last year, 1991 was the first year that most of the objectives were checked. Fecal coliform and enterococci objectives, set to protect bathing beaches, were not met in Westbank Creek. Other objectives that were exceeded included those for dissolved aluminum in Peachland, Trepanier, and Westbank creeks, molybdenum in Peachland Creek, and iron at the mouth of Westbank Creek.

Objectives met included those for dissolved solids, sodium, and pH in Peachland and Trepanier creeks; ammonia, nitrate, and nitrite in Peachland and Westbank creeks; chlorophyll-a in Peachland Creek; dissolved oxygen and copper in Westbank Creek; and molybdenum in Trepanier creek.

Continued monitoring to check objectives will be a high priority in this basin for the next few years.

9.7 Tributaries to Okanagan Lake near Kelowna

Data and site locations are presented in Table 19 and Figure 19, respectively.

Mission, Kelowna, and Brandt's creeks are tributaries to Okanagan Lake on its east shore near Kelowna. Mission and Kelowna creeks support salmonids and the water is also used for irrigation and domestic supply. Brandt's Creek is used mainly for just irrigation. The creeks can be affected by urban stormwater runoff in their lower reaches and by logging or agriculture further upstream. Treated wastewater is discharged to Brandt's Creek.

As for the tributaries near Westbank (section 8.6), 1991 was the first year of relatively complete monitoring to check objectives. The objectives for fecal coliforms, E. coli, and enterococci were generally not met in Mission and Kelowna creeks (a similar result to 1990). Other objectives exceeded included those for specific conductivity in Brandt's Creek (met in 1990) and for chlorophyll-a in Mission Creek.

All other objectives checked were met. These included ammonia, nitrite, and dissolved oxygen in Kelowna and Mission creeks; chlorophyll-a in Kelowna Creek; and metals (aluminum, copper, lead, and zinc) also in Kelowna Creek.

9.8 Hydraulic Creek

Data and site locations are presented in Table 20 and Figure 20, respectively.

Hydraulic Creek flows into Okanagan Lake via Mission Creek about 10 km upstream from the lake. Hydraulic Creek is an important source of drinking water relying on disinfection only. The creek also supports recreational fish and is used for irrigation. Commercial logging in the watershed can affect these water uses.

In 1991, objectives were checked for the first time and fairly complete measurements were obtained. The only objective to be

exceeded was the one for temperature at the outlet of Hydraulic Lake for one week. All other objectives were met. These included objectives for turbidity, suspended solids, temperature for virtually all of the summer, and fecal coliforms. Objectives for E. coli and enterococci were not checked in 1991.

Monitoring to check objectives in Hydraulic Creek will remain a priority for the next few years to establish a reasonable data base.

10. KOOTENAY REGION

10.1 Columbia and Windermere Lakes

Data and site locations are presented in Table 21 and Figure 21, respectively.

The two lakes are important for fisheries, recreation, and as a source of drinking water. Housing development around the lakes is the main potential influence on water quality.

The pattern in the past has been for all objectives set in the lakes to be met. In 1991, the only objectives checked were those for fecal coliforms at Windermere Lake beaches and they were met. Objectives not checked included those for fecal coliforms at water intakes, phosphorus at spring overturn, and turbidity.

Monitoring to check objectives has been carried out since 1987, although not all objectives were checked each year. Since the objectives have been met fairly consistently, future monitoring is a low priority at this time.

10.2 Toby Creek and Upper Columbia River

Data and site locations are presented in Table 22 and Figure 22, respectively.

Toby Creek enters the Upper Columbia River just downstream from Windermere Lake. Both streams are important for aquatic life and recreation. Toby Creek can be affected by indirect discharges of domestic sewage and by drainage from an abandoned mine. The Upper Columbia River receives a discharge of treated sewage from Radium Hot Springs.

In the Upper Columbia River, the fecal coliform objective to protect drinking water upstream from Radium was not met, whereas the objective to protect recreation downstream from Radium was met. These results are similar to results obtained intermittently in the past since 1987. In Toby Creek, the objectives were last checked in 1988 and 1989. All objectives were met except, on one occasion, those for fecal coliforms. Objectives met included those for suspended solids, nutrients, and certain metals.

Although objectives have not been strictly checked completely over three years, future monitoring is considered a fairly low priority considering results obtained so far.

10.3 Columbia River from Keenleyside to Birchbank

Data and site locations are presented in Table 23 and Figure 23, respectively.

The Columbia River is one of the major rivers in British Columbia and further downstream in the United States. In B.C., the river is important for aquatic life, sport fishing, recreation and, to a lesser extent, as a drinking water supply. In the U.S., it supports a food fishery, major salmon runs, and irrigation and drinking water supplies. In the section of river from the Hugh Keenleyside Dam to Birchbank, the main influence is a kraft pulp mill discharging effluent about 3 km downstream from the dam. The mill is being expanded and modernized and the effluent treatment upgraded to secondary. There are also small discharges of secondary-treated municipal effluent.

Objectives were checked for the first time in 1991 and monitoring was reasonably complete. Objectives met included those for pH, colour, suspended solids, turbidity, pulp mill toxicity in the river, chlorophenols, resin acids, and chlorinated resin acids.

The objective for dioxins and furans in fish were not met. A public notice advising against consumption of mountain whitefish from the river was issued in 1990. This situation is expected to improve after modernization of the pulp mill. The objective for total dissolved gases was exceeded for well over half the year. Changes in the way the Hugh Keenleyside dam is operated will be required in order to meet the objective at all times. The objective for dissolved oxygen was exceeded on a few occasions, although all recorded values were greater than 9.4 mg/L.

There were insufficient data to check fecal coliform and E. Coli objectives and the results for dioxins and furans in water were indefinite due to high detection limits. Objectives for total organic carbon in sediment, dioxins and furans in sediments, and for chlorophyll-a were not checked in 1991.

11. LOWER MAINLAND REGION

11.1 Fraser River from Hope to Kanaka Creek

Objectives have been set for the Fraser River, for tributaries entering from the south, and for all major water courses between the Fraser River and the International Border. The Fraser River is a major salmon migration route and the tributaries are important spawning areas. The major discharges to the Fraser River in this section are of treated sewage.

Monitoring to check objectives was carried out in 1987, 1988, and 1990 and discontinued in 1991. The results showed that the fecal coliform objective was met in the Fraser River and in some tributaries, but exceeded in certain other tributaries. Objectives for dissolved oxygen and ammonia were usually met in the river, except at times immediately downstream from the Chilliwack sewage treatment plant.

Considering the importance of the Fraser River, past results, and the intermittent nature of the monitoring, at least one more year of complete monitoring should be carried out.

11.2 Fraser River from Kanaka Creek to the Mouth

Data and site locations are presented in Table 24 and Figure 24, respectively.

The river and outer estuary are important for salmon migration and rearing. The water is used for irrigation and certain beaches are important for recreation. Water quality can be affected by major discharges of municipal and industrial effluents.

Monitoring to check objectives has been carried out annually

since 1987. Due to the provincial importance attached to the river and the threats to water quality that exist in this section, such monitoring will be continued.

The fecal coliform objective, set to protect irrigation, was met in the Main Stem, the North Arm, and the Middle Arm. In the Main Arm, it was not met at times downstream from Annacis. The objective to protect swimming was met at all points along Iona beach and Tsawwassen beach. All coliform results were similar to those obtained in 1988, 1989, and 1990.

The maximum ammonia objective was met in the Main Arm, the North Arm, and the Middle Arm. The dissolved oxygen objective was met in the Main Stem and in all the river arms. It was not checked in the sloughs (although in 1989 it was exceeded at times in Gunderson, Deas, Ladner, and MacDonald sloughs) or on Sturgeon Bank and Roberts Bank.

The pH objective was occasionally exceeded in the Main Stem and in the river arms when slightly lower values were recorded. Only a few data on total metals were collected in 1991. The maximum objective for copper was exceeded in the Main Arm downstream from Annacis. Such higher copper values have occurred at times in the past in the Main Arm. The maximum objectives for lead and zinc were met in all the river arms.

The objective for chlorophenols in sediments was met in Gunderson Slough and Tilbury Slough in the Main Arm and at sites downstream from Belkin in the North Arm. This result confirms those of 1990 which showed a definite improvement over 1989 when the objective was exceeded in the Main and North arms. The objective for PCBs in sediments was met in the Main and North arms, as it was in 1990 and 1989.

11.3 Boundary Bay

Data and site locations are presented in Table 25 and Figure 25, respectively.

Boundary Bay sustains a crab and herring fishery and is important for recreation. The little Campbell River, the Serpentine River, and the Nicomekl River are tributaries to Boundary Bay on the east side. They provide important habitat for trout and salmon and are used for irrigation.

The fecal coliform objectives to protect bathing beaches were met in Boundary Bay in 1991, including at sites in White Rock where the objectives have been exceeded at times in the past. In the tributary rivers, the objective to protect irrigation use was not checked. In the past, the objective was usually met in the main stem of the rivers and exceeded at times in their tributaries.

The objective for suspended solids was exceeded the one time it was measured in Boundary Bay near a pump station. The objective for turbidity was met at the same site. These objectives were not checked in the tributary rivers although they have been exceeded at times in the past, in the September to October period.

The substrate sedimentation objective was not checked, although it had been in 1990 and 1989. The objective was met in some streams and exceeded in others, usually near the mouths.

The maximum objective for ammonia was met in the tributary streams as it generally has been in the past. The dissolved oxygen objective was exceeded on one occasion in Boundary Bay, the only place it was measured. In the past, the objective has been frequently exceeded both in Boundary Bay and in certain of the tributaries due, presumably, to agricultural runoff. No other objectives were checked in 1991. Objectives for toxic substances

such as those for lead in the Nicomekl River and PCBs in the sediments of Boundary Bay and the tributaries have been met in the past.

Monitoring to check objectives has been carried out from 1988 to 1991, although not completely every year. Considering the length of record and the consistency of results, further monitoring is a low priority at this time.

11.4 Burrard Inlet

Data and site locations are presented in Table 26 and Figure 26, respectively.

Burrard Inlet includes Port Moody Arm, Indian Arm, Vancouver Harbour, False Creek, and English Bay. The water is designated for aquatic life and wildlife in all areas and for primary-contact recreation in most areas, except in False Creek. There are several municipal and industrial discharges to Burrard Inlet which can affect water quality. These include primary-treated sewage, combined sewer overflows, stormwater, bulk-loading terminals, a sugar refinery, a sodium chlorate plant, a chlor-alkali plant, and oil refineries.

This is the second year that objectives for Burrard Inlet have been checked and monitoring was fairly complete in comparison to 1990.

Extensive data were collected for fecal coliforms at bathing beaches. Samples of the data are given in Table 26. The objective was exceeded at times at Brockton Point but met at other beaches. These included beaches in Port Moody Arm, Indian Arm (sometimes exceeded in 1990), near 2nd. Narrows, in West Vancouver, around English Bay, and at the mouth of False Creek. The enterococci objective, which was not tested as extensively, was exceeded at

times in Indian Arm and at Ambleside Beach but met elsewhere.

The objectives for suspended solids and turbidity were tested using Indian Arm as a control site. The objectives were generally met except occasionally near a chlor-alkali plant and near a major combined sewer overflow.

The ammonia objectives were met throughout Burrard Inlet. The objective for dissolved oxygen was frequently not met at all sites tested, although the minimum value rarely dropped below 5 mg/L. These measurements were made in the summer thereby presenting a worst case for dissolved oxygen values. The cyanide objective, applicable only to Port Moody Arm, was generally considered met except on one occasion near a bulk-loading terminal. The pH objective, applicable between 2nd. Narrows and Roche Point, was met.

The objective for arsenic was met at all sites tested, both in the water and in the sediments. Objectives for a number of heavy metals in water and sediments were set for various locations. Results can be summarized as follows:

- in water, objectives for barium, cadmium, chromium, nickel, and zinc were met. Objectives for lead and iron were exceeded occasionally while those for copper and mercury were exceeded at most sites.

- in sediments, objectives for chromium, and nickel were met while those for cadmium, copper, lead, mercury, and zinc were often not met. High values occurred near oil refineries and combined sewer overflows. In general, there is a trend for heavy metals to exceed objectives more in the sediments than in the water column. Although the mercury objectives in water and sediments were exceeded, the mercury objective for fish was met in English sole from False Creek and off Locarno Park.

Objectives have been set for a number of organic compounds,

none of which were checked in 1990. In 1991, the objective for PCBs was exceeded in sediments from Vancouver Harbour and False Creek and in fish from False Creek. The objective for phenols was not met on several occasions in the Harbour and in Port Moody Arm. For PAHs, objectives are set for individual PAHs in sediments and are grouped as either low molecular weight (L-PAH) or high molecular weight (H-PAH) compounds. At the two ends of Burrard Inlet, namely Port Moody Arm and Outer Burrard, all the objectives were met in the sediments except for a few high molecular weight compounds. At the other extreme, in False Creek, all the objectives were exceeded. In the remaining waters of Burrard Inlet there were mixed results with more objectives for high molecular weight compounds being exceeded in Vancouver Harbour. Results for tributyl tin were indefinite due to high detection limits and objectives for chlorophenols, ethylene dichloride and styrene were not checked.

11.5 Burrard Inlet Tributaries

Data and site locations are presented in Table 27 and Figure 27, respectively.

Objectives were set for three tributaries to Burrard Inlet. School House Brook discharges to Port Moody Arm and could be influenced by a chemical polymer plant. Lynn Creek discharges to Vancouver Harbour and could be affected by a municipal landfill. The Capilano River discharges to outer Burrard Inlet and may also be affected by a municipal landfill. The main uses of these tributaries are recreation, aquatic life, and wildlife.

The objectives were checked for the first time in 1991 but the results are very incomplete. The objective for fecal coliforms was met in Lynn Creek. The results for the Capilano River, where the objective also applies, were indefinite. The objectives for ammonia and nitrite were met in Lynn Creek and the Capilano River.

Regarding heavy metals, only two objectives were checked. Those for copper were exceeded on one occasion in School House Brook and the Capilano River but met in Lynn Creek. Those for mercury were met in Lynn Creek and the Capilano River.

Objectives not checked included those for chlorophyll-a, dissolved oxygen, phenols, temperature, pH, cadmium, chromium, cobalt, iron, lead, zinc, mercury in fish, chlorophenols in water and sediments, and PCBs in water, sediments, and fish.

11.6 North Shore Lower Fraser Tributaries

Data and site locations are presented in Table 28 and Figure 28, respectively.

Objectives have been set for the following four tributaries to the north shore of the lower Fraser River in the Lower Mainland: Kanaka Creek, the Pitt River, the Coquitlam River, and the Brunette River. All these streams, and their tributary streams and lakes, support salmon and trout fisheries to varying degrees. Most are important for recreation and some are sources of drinking water requiring treatment. Discharges which can affect water quality include stormwater, agricultural runoff, treated sewage, landfill leachates, wastewaters from gravel operations, and a wood preservation plant.

Fecal coliform, E. coli, and enterococci objectives were exceeded in most streams. These included Kanaka Creek, the Pitt River, the Alouette River, the North Alouette River, the Coquitlam River, and Or Creek (a tributary to the Coquitlam River). In Scott Creek (another tributary to the Coquitlam) and Hoy Creek (a tributary to Scott), the fecal coliform objective was met but those for E. coli and enterococci were exceeded. Only in Pitt Lake were the objectives for all three microbiological objectives met. In Alouette Lake, the objective for enterococci was exceeded but those

for fecal coliforms and E. coli were met. These results are in contrast to those of 1990 when the objectives were generally met in the Pitt River, the Alouette River, the North Alouette River, the Coquitlam River, and Or Creek.

The objective for suspended solids was exceeded at times in Kanaka Creek, the Pitt River, and the Coquitlam River. It was met in the other streams and lakes, although there were a number of indefinite results due to a lack of control sites. The turbidity objective was also exceeded in Kanaka Creek, the Pitt River, and the Coquitlam River as well as in the Alouette and North Alouette rivers. There were a similar number of indefinite results due to a lack of control sites. The substrate sedimentation objective was not checked in 1991. It was exceeded last year in the Brunette River, the only location where it was checked.

The objectives for ammonia and nitrite were met in all streams and lakes. The objective for chlorophyll-a was not checked, although it was met in all areas checked in 1990. The dissolved oxygen objective was generally met, except at times in Kanaka Creek, the Alouette and North Alouette rivers, the Coquitlam River, Scott Creek, Hoy Creek, Burnaby Lake, and Deer Lake. Despite these results, the dissolved oxygen level was not recorded below 6.7 mg/L in the streams. The pH objective was met throughout, except a few times in Kanaka Creek when slightly lower values were recorded.

Some heavy metal objectives were exceeded at times in the Brunette River drainage. Among objectives not met were those for copper in Still Creek, Burnaby Lake, the Brunette River, and Deer Lake; lead in Burnaby and Deer lakes; and zinc in Still Creek and Burnaby Lake. The objectives for chromium and mercury were met throughout the system. In sediments, the objectives for copper, lead, and zinc were exceeded in Stil Creek and the Brunette River. In addition, the sediment lead objective was exceeded in Burnaby Lake and Deer Lake and the sediment zinc objective was exceeded in

Burnaby Lake. The mercury sediment objective was not checked nor were the objectives for lead and mercury in fish from the Brunette River drainage.

The objectives for chlorophenols in water and sediments were met in the Pitt River, an improvement over 1990 when the objective for chlorophenols in sediments was exceeded. The objective for chlorophenols in fish was not checked in 1990 or 1991.
