

**INTERCEPTION OF SKEENA RIVER
SOCKEYE SALMON STOCKS IN
NORTHERN BOUNDARY MARINE FISHERIES**

Introduction

This report is in partial fulfillment of a contract with SkeenaWild Conservation Trust to estimate the marine interception of Skeena River sockeye salmon stocks in Northern Boundary fisheries (Canada and U.S., see Figure 1). The approach is to expand the Northern Boundary Reconstruction Model (NBRM, Gazey and English 2000) such that the Skeena aggregate is partitioned into 14 stocks.

Methods

The Skeena River sockeye stocks were defined by geographical aggregates or mainstream river sections into which spawning streams drain (see Gazey 2001) and constancy in the timing of returning runs associated with the rearing lakes (Cox-Rogers 2005). Table 1 lists the subsequent stock definitions and the associated rearing lakes (see Figure 2). The Coastal stock was not assessed as part of the Skeena system by Cox-Rogers (2005); however, the stock is part of the Skeena aggregate in the NBRM.

The main assumptions required for this analysis are:

- (1) Non-Babine escapement counts are subject to an expansion of 2.59 because of a bias from visual surveys. The factor was derived from the 1999 and 2000 Tye Test Index DNA data and was used to estimate the aggregate Skeena run at the mouth of the river for the NBRM (LGL 2008). The following non-Babine systems were not expanded because the counts were reliable: Moricetown fishway, Slamgeesh fence, Kitwanga fence and the Sustut/Johanson fence.
- (2) All stocks are equally vulnerable to harvest in-river.
- (3) The Babine stocks (wild and enhanced) have the same timing and run distribution as the Skeena aggregate.
- (4) All non-Babine stocks have normal run distributions at the Skeena mouth.
- (5) All stocks have the same migration route through marine waters as the Skeena aggregate defined by the NBRM.

In-River Reconstruction

Assumptions (1) and (2) applied to the escapement by system (lake, river or stream) provided by Steve Cox-Rogers of DFO (file 4esc.xls) and in-river catch data provided by Richard Alexander of LGL Limited (file inriver.xls) enabled the run reconstruction and subsequent estimation of the percent by stock each year at the river mouth.

First, systems not passing through the Babine fence were inflated by a factor of 2.59 to account for visual bias. Some of the systems were not inflated because the escapement counts were considered reliable; namely: Moricetown fishway, Slamgeesh fence starting in 2000, Kitwanga fence starting in 2000, and Sustut fence starting in 1992. Escapement records for a system that did not have a valid escapement observation for the 1982 to 2006 period were ignored. Next, the escapement data for 1982 to 2006 were amalgamated according to the stock definitions (see Table 2); however, for many data records, escapements were not observed or the counts were considered too uncertain to record. It is important to observe that the missing surveys are more likely to re-occur in particular systems usually of limited spawning potential, i.e., the missing surveys do not occur at random. The missing escapement was estimated for system i and year j (\hat{E}_{ij}) using a simple missing data algorithm that is useful in dealing with highly heterogeneous (non-random) distributions (see Little and Rubin 1987), that is,

$$(1) \quad \hat{E}_{ij} = \rho_i \frac{\sum_j I_{ij} E_{ij}}{\sum_j I_{ij} \rho_i},$$

where E_{ij} is the escapement for system i in year j , I_{ij} is an indicator variable that has a value of 1 if an escapement measure is valid and 0 otherwise, and the mean escapement proportion for a system (ρ_i) is defined by

$$\rho_i = \frac{\sum_j I_{ij} E_{ij}}{\sum_i \sum_j I_{ij} E_{ij}}.$$

Next, Morrison, wild Babine and enhanced Babine stocks were prorated such that their sum equaled the Babine fence count minus any removals at or after passing the fence for each year.

The in-river catch data were grouped or prorated using historical information available into mixed stock fishing regions (see Table 3). The catch was assigned to stocks using the single time step (annual) reconstruction algorithm described by Starr and Hilborn (1984), the run size at the river mouth by stock was estimated (catch plus escapement) and the percent stock composition calculated.

Marine Reconstruction

Assumptions (3), (4) and (5) enabled the marine reconstruction of catch contributed by the Skeena stocks by an amended NBRM, i.e., the Skeena aggregate catch estimated by the NBRM was partitioned into the Skeena stocks defined in Table 1. The NBRM requires the input of the escapement by stock leaving the marine area (i.e., the run size at the Skeena mouth) and the temporal distribution for each stock.

The run size by stock at the Skeena mouth was estimated as the simple product of total aggregate escapement to the Skeena mouth used by the NBRM and the stock compositions estimates described above. With respect to the temporal distributions, assumption (3) specifies that the Babine stocks (wild and enhanced) track the aggregate and, by assumption (4), all others are normally distributed. I further assumed that non-Babine timing location (early-late) is correlated with the aggregate mean (or peak) date. In other words, all stocks tend to be earlier or later in a given year. The timing information from Cox-Rogers (2005) was used to specify the offset from the aggregate mean and the associated standard deviation to define the normal distributions (see Table 4). The Coastal stock was assumed to have the same timing characteristics as the Lower Skeena above Kasiks stock (Alaistair and Lakelse lakes).

The NBRM could have been applied to the Skeena stocks with minimal amendment to the code by replacing the Skeena aggregate with the 14 Skeena stocks. However, this approach would have resulted in copious output, not of interest to other users, and a significant degradation in model execution. Instead, the NBRM was

amended to allow an option for the breakout of Skeena stocks and, if selected, input a table in the Microsoft Access© database containing the information described above, compute the catch allocation to Skeena stocks based on a simple and efficient algorithm, and output two additional files containing the annual and weekly Skeena summaries.

The newly created Microsoft Access© table (SXSkeena) input by NBRM contains the following fields: year, stock number, stock name, offset, standard deviation, and percent stock composition. For this analysis the stock definitions, timing offset and timing deviations are the same for all years; however, the model allows the entry of any year specific values (i.e., different stock definitions and migration timings).

Assumption (4) allowed the construction of a simplified and efficient catch allocation for the Skeena stocks. Since the migration route is the same for all stocks, since the NBRM partitions the Skeena aggregate into unique migration routes, and since the fish are assumed to move at the same speed (but can travel different distances through the marine fisheries), the stock composition of Skeena fish caught traveling on a unique migration route during a particular day and fishery depends only on the stock composition of the escapement at the Skeena mouth that would have been vulnerable during that particular day. Thus, catch allocations for the Skeena aggregate on a particular day, migration route and fishery, can be distributed to the 14 stock components based solely on the stock composition when the caught fish would have reached the Skeena mouth.

Results

The estimated escapements, amalgamated by stock, adjusted for missing surveys and adjusted for visual count bias, required to seed the in-river annual reconstruction are listed in Table 5. Also, displayed in Table 5 is the terminal catch (consists only of fish produced by the Bulkley/Morice stock) taken from the Bulkley River. In-river reconstructed catch estimates are provided in Table 6 and the subsequent total run at the river mouth estimates are shown in Table 7. The ensuing stock composition estimates are given in Table 8.

Annual catch, harvest rate, escapement, run size and exploitation rate summaries for 1982 to 2006 using the multi-period NBRM with all available stock identification information are presented in Tables 9 to 33.

Discussion

The following comments are pertinent to the estimation of the percent stock composition using the annual in-river reconstruction:

1. The escapement surveys are characterized by yearly variation (some years are good or poor for sockeye returns) and valid surveys tend to favour the systems with larger returns and vice versa. The missing escapement algorithm (equation 1) is sensitive to both of these characteristics (Little and Rubin 1987).
2. Surveys on wild systems and spawning channel were used to partition the Babine fence count, minus any removals at or above the fence, into wild, enhanced and Morrison stock components. Since the spawning channels are easier to survey than the wild systems, wild Babine and the Morrison stock compositions are likely underestimated.
3. The expansion of non-Babine stocks to correct underestimation from visibility problems serves mainly to impact the composition between Babine and non-Babine stocks but has less impact within the non-Babine composition. The reliable, not inflated non-Babine escapement counts (Moricetown, Slamgeesh, Kitwanga and Susutut) only account for about 10%, on average, of the non-Babine population.
4. Any unequal vulnerability of stocks to in-river harvest likely has minimal impact on the stock composition estimates. The in-river catch is relatively small with an average removal of 17%, approximately, of the run size returning to the Skeena mouth. Of that catch, about 43% is taken on the main-stem above Fiddler Creek where only 5 of the 12 non-Babine stocks are subject to harvest; 35%, approximately, is taken at or above the Babine fence where only one non-Babine stock is vulnerable; and, only 18%, approximately, is taken below Fiddler Creek where all 12 non-Babine stocks are potentially vulnerable.
5. The methodology is consistent with the NBRM to determine the Skeena aggregate run size at the mouth of the Skeena River

The reliability of the stock composition estimates depends mainly on the extent that the escapement surveys, adjusted for missing surveys and visibility biases, are reliable indices of escapement. The precision and the accuracy of the stock composition estimates are unknown. Direct and comprehensive measures of stock composition from genetic sampling at the Skeena mouth for comparison and/or replacement would be of significant value.

The three assumptions made for the marine reconstruction through the NBRM are consistent with those made by Cox-Rogers (2005). The assumption that all stocks have the same migration routing as the Skeena aggregate is highly suspect; however, there is no basis for an alternative assumption. In order to extract useful information in the absence of reliable escapement estimates, Cox-Rogers (2005) uses aggregate Skeena harvest rates and timing curves for individual Skeena stocks to infer exploitation rates. Similarly, the exploitation rates calculated here (Tables 8 to 33) are a function of the daily aggregate Skeena harvest rates in fisheries and the assumed timing curves (i.e., the exploitation rates do not depend on the stock composition at the mouth of the Skeena River). However, the exploitation rates can only be put into context through some knowledge of run strength and productivity. In other words, stock assessment requires catch and escapement to be assigned to a stock. This analysis is a direct attempt to accomplish that task.
