Canadian Manuscript Report of Fisheries and Aquatic Sciences No. 2646

## Canadian Manuscript Report of Fisheries and Aquatic Sciences

Manuscript reports contain scientific and technical information that contributes to existing knowledge but which deals with national or regional problems. Distribution is restricted to institutions or individuals located in particular regions of Canada. However, no restriction is placed on subject matter, and the series reflects the broad interests and policies of the Department of Fisheries and Oceans, namely, fisheries and aquatic sciences.

Manuscript reports may be cited as full publications. The correct citation appears above the abstract of each report. Each report is abstracted in Aquatic Sciences and Fisheries Abstracts and indexed in the Department's annual index to scientific and technical publications.

Numbers 1-900 in this series were issued as Manuscript Reports (Biological Series) of the Biological Board of Canada, and subsequent to 1937 when the name of the Board was changed by Act of Parliament, as Manuscript Reports (Biological Series) of the Fisheries Research Board of Canada. Numbers 1426-1550 were issued as Department of Fisheries and the Environment, Fisheries and Marine Service Manuscript Reports. The current series name was changed with report number 1551.

Manuscript reports are produced regionally but are numbered nationally. Requests for individual reports will be filled by the issuing establishment listed on the front cover and title page. Out-of-stock reports. will be supplied for a fee by commercial agents.

## Rapport manuscrit canadien des sciences halieutiques et aquatiques

Les rapports manuscrits contiennent des renseignements scientifiques et techniques ques qui constituent une contribution aux connaissances actuelles, mais qui traitent de problèmes nationaux ou régionaux. La distribution en est limitée aux organismes et aux personnes de régions particulières du Canada. Il n'y a aucune restriction quant au sujet; de fait, la série reflète la vaste gamme des intérêts et des politiques du ministère des Pêches et des Océans, c'est-à -dire les sciences halieutiques et aquatiques.

Les rapports manuscrits peuvent être cités comme des publications complètes. Le titre exact paraît au-dessus du résumé de chaque rapport. Les rapports manuscrits sont résumés dans la revue Résumés des sciences aquatiques et halieutiques, et ils sont classés dans l'index annual des publications scientifiques et techniques du Ministère.

Les numéros 1 à 900 de cette série ont été publiés à titre de manuscrits (série biologique) de l'Office de biologie du Canada, et après le changement de la désignation de cet organisme par décret du Parlement, en 1937, ont été classés comme manuscrits (série biologique) de l'Office des recherches sur les pêcheries du Canada. Les numéros 901 à 1425 ont été publiés à titre de rapports manuscrits de l'Office des recherches sur les pêcheries du Canada. Les numéros 1426 à 1550 sont parus à titre de rapports manuscrits du Service des pêches et de la mer, ministère des Pêches et de l'Environnement. Le nom actuel de la série a été établi lors de la parution du numéro 1551.

Les rapports manuscrits sont produits a l'échelon régional, mais numérotés à l'échelon national. Les demandes de rapports seront satisfaites par l'établissement auteur dont le nom figure sur la couverture et la page du titre. Les rapports épuisés seront fournis contre rétribution par des agents commerciaux.

#### Abstract

Baxter, B.E. 2003. Adult and juvenile coho salmon enumeration and coded-wire tag recovery analysis for Zolzap Creek, BC, 2002. Can. Manusc. Rep. Fish. Aquat. Sci. 2646: vii +44 p.

Adult and juvenile coho migrations were monitored at Zolzap Creek, British Columbia, as part of the 2002-2003 Nisga'a Fisheries Program. The 2002 season is the eleventh year of continuous operation of the Zolzap Creek fences since 1992. This report includes eleven year summaries of the most pertinent data. Smolt trapping was conducted from 29 April to 26 June 2002 using an in-stream wire-mesh fence. A total of 15,001 coho smolts were captured during the trapping period, and an unknown number migrated out during periods when the fence was not operational. Of those captured, 12,318 were released with coded-wire tags. Migration timing, mean length and weight at age, and age composition are presented.

Adult coho escapement was monitored using an in-stream fence and carcass surveys. The counting fence was operational between 21 August and 5 October. A total of 1,918 adult coho were counted at the fence with an estimated escapement of 3,233 using the adjusted Peterson model. Adipose clip rate was $46.4 \%$ for adult coho. Age and length characteristics of adult males and females are presented.

Canadian and US commercial harvests were examined using coded-wire tag recovery data obtained from the Mark-Recovery Program and the Alaska Department of Fish and Game (ADF\&G) mark tag and age lab online searchable database. Total exploitation rate on Zolzap Creek coho in 2002 was $19.9 \%$ ( $3.3 \%$ Canadian, $16.6 \%$ US). Of the total commercial catch of Zolzap Creek coho, Canadian catch accounted for $16.5 \%$ and the US catch accounted for an estimated $83.5 \%$. Harvests occurred over a wide area ranging from SE. Alaska to the US Northern Outside Statistical Area in Alaska (northwest of Juneau, AK). Limited Canadian commercial harvests occurred in Areas 1-5 for Zolzap Creek in 2002. US harvests of Zolzap coho in Alaska were largest in the Southern Inside Statistical Area for the net fishery and the Central Outside Statistical Area for the troll fishery. Total survival was $8.4 \%$ and smolt-tospawner survival was $6.7 \%$.

## RÉSUMÉ

Baxter, B.E. 2003. Adult and juvenile coho salmon enumeration and coded-wire tag recovery analysis for Zolzap Creek, BC, 2002. Can. Manusc. Rep. Fish. Aquat. Sci. 2646: vii +44 p.

Les migrations de saumons coho, adultes et jeunes, ont été mesurées au ruisseau Zolzap en Colombie-Britannique, dans le cadre de la Stratégie des pêcheries autochtones des Nisga'a en 2002-2003. L'année 2002 marque la 1 lième saison d'opération continue des barrières en fil métallique du ruisseau Zolzap depuis 1992. Ce rapport contient 11 ans de sommaires des données les plus intéressantes. Le piégeage des saumoneaux prit place entre le 29 avril et le 26 juin 2002 à l'aide d'une barrière en fil métallique installée dans le ruisseau. En tout, 15,001 saumoneaux coho ont été capturés pendant la période de piégeage tandis qu'un nombre inconnu a migré quand la barrière n'était pas opérationelle. Sur l'ensemble des saumoneaux capturés, 12,318 ont été remis à l'eau avec une marque magnétique codée. La période de migration, la longueur moyenne, le poids et la composition selon l'âge sont présentées.

L'échappée de saumons coho adultes a été surveillée grâce à une barrière installée dans le ruisseau et à l'observation des carcasses. La barrière de comptage fut opérationelle entre le 21 août et le 5 Octobre. Un total de 1,918 saumons coho adultes ont été dénombrés à la barrière avec une échappée estimée à 3,233 utilisant le model Peterson ajusté. Le taux d'ablation de la nageoire adipeuse était de $46.4 \%$ pour les saumons coho adultes. Nous présentons les caractéristiques d'âge et de longueur pour les mâles et les femelles adultes.

Les récoltes commerciales canadiennes et américaines ont été examinées grâce aux données de récupération des marques magnétiques codées provenant du Programme de marquage-récupération et en direct de la base de données du Département de Pêche et Chasse de l'Alaska. En 2002 le taux total d'exploitation commerciale de saumon coho au ruisseau Zolzap fut évalué à $19.9 \%$ ( $3.3 \%$ pour le Canada, $16.6 \%$ pour les États-Unis). Sur le total de prises commerciales de saumon coho au ruisseau Zolzap, le Canada en comptait $16.5 \%$ et les ÉtatsUnis, une estimation de $83.5 \%$. Les récoltes couvraient un vaste secteur, s'étendant à partir du sud-est de l'Alaska jusqu'à la zone statistique nord extérieure de l'Alaska aux États-Unis (au nord-ouest de Juneau, AK). Des récoltes commerciales Canadiennes limitées ont prit place dans le secteur 1-5 pour le ruisseau Zolzap in 2002. Les saumons coho du Zolzap récoltés par les États-Unis en Alaska furent plus nombreux dans la zone statistique sud intérieure pour la pêche au filet, et, dans la zone statistique centrale extérieure pour la pêche à la traîne. Le taux total de survie fut $8.4 \%$ tandis que pour les saumoneaux/géniteurs le taux de survie fut $6.7 \%$.

## INTRODUCTION

As part of the Aboriginal Fisheries Strategy (AFS), a program was established for fisheries research in the Nisga'a Traditional Territory, British Columbia. One component of this large research initiative focused on the assessment of juvenile and adult coho populations in tributaries to the Nass River. Juvenile and adult coho enumeration studies have been conducted on Zolzap Creek since 1992 (Nass 1996a; Nass 1996b; Nass 1996c; Nass and English 1994; Nass 1997a; Nass 1997b; Nass 2001; Nass and Frith 2001; Baxter et al. 2001; Baxter and Stephens 2002, Baxter and Stephens 2002a, Baxter and Stephens 2002b). This report presents results for studies conducted at Zolzap Creek in 2002.

The objectives of the research were to:

1. Enumerate migrating juvenile coho and estimate escapement;
2. Document the timing, size, and age distribution of migrating coho;
3. Mark coho smolts with coded-wire tags (CWT) to enable the determination of oceanic harvest rates;
4. Monitor the escapement for marked CWT adult coho, and determine ocean exploitation and survival rates; and
5. Collect water temperature and level data for future examination of the relationships between physical environmental factors and coho smolt migration timing, and between adult escapement and smolt production.

Achievement of these objectives involved the construction and operation of in-stream, semi-permanent, panel fences located approximately 0.5 km upstream of the mouth of Zolzap Creek.

## STUDY STREAM

Zolzap Creek is a tributary to the Nass River, located in northwestern British Columbia (Figures 1 and 2). Zolzap Creek flows for 6 km in a northwesterly direction between Nisga'a Lava Bed Memorial Park and the Kitimat Mountain Range to its confluence with the Nass River, 5 km downstream of Gitwinksihlkw. The main channel of the creek is regularly interrupted by beaver dams and $\log$ jams. The substrate is highly variable and ranges between silty particulate, to granite cobble, and coarse pumice. Major flow contributions come from Lava Creek ( 3 km in length) which flows from the lava beds and numerous small creeks that flow from the steep alpine. Intermittent flows of water from the Nass River and Vedder Creek are possible during flooding periods. The mouth of Zolzap Creek enters a side channel to the Nass River known as Zolzap Slough. The lower 0.5 km of Zolzap Creek regularly becomes inundated when water levels on the Nass River are high. Zolzap Creek supports many species of salmonids including coho (Oncorhynchus kisutch), pink (O. gorbuscha), chum (O. keta), sockeye (O. nerka), rainbow
(O. mykiss), cutthroat (O. clarki), and Dolly Varden (Salvelinus malma). Non-coho species include lampreys (family Petromyzontidae), sticklebacks (family Gasterosteidae), and sculpins (family Cottidae). Coho escapement was estimated to be 1,561 in 1992 (Nass 1996b), 1,048 in 1993 (Nass 1996c), 2,536 in 1994 (Nass 1997a), 908 in 1995 (Nass 1997b), 1,039 in 1996 (Nass 2001), 470 in 1997 (Nass and Frith 2001), 967 in 1998 (Baxter et al. 2001), 1,393 in 1999 (Baxter and Stephens 2002), 456 in 2000 (Baxter and Stephens 2002a), and 1,897 in 2001 (Baxter and Stephens 2002b).

## JUVENILE COHO STUDIES

## METHODS

## Trapping Operations

An in-stream, semi-permanent enumeration fence was located 0.5 km upstream of the creek mouth for the capture of downstream migrating coho smolts. Fence design was based on Conlin and Tutty (1979) and minor modifications were required due to site characteristics and available materials. The fence was built in a W-pattern and spanned the entire creek bed. Three by eight foot panels constructed of $2 \times 4$ 's and covered with $1 / 4^{\prime \prime}$ wire-mesh were laid on their long side in the creek bed to form the fence. Rebar of $3 / 8^{\prime \prime}$ and $1 / 2^{\prime \prime}$ diameter were used to anchor the panels to the stream bed. A second layer of panels were installed on top of the first row of panels to create a fence with a total height of six feet. Burlap sandbags and heavy duty plastic garden sheeting were used to seal the base of the panels. Two hinged panels were installed in each of the fence wings for release of excess water in the event of flooding. Plywood trap boxes with Vexar-screened windows (to allow water exchange) were anchored at each down-stream apex and were connected to the fence with 8 " Big-O tubing. Additional boxes were made for holding fish after processing and were designed with a small door for releasing fish. Provisions for upstream migrating adults were made by constructing a simple trap consisting of a wire-mesh panel extending out from the stream bank to one wing of the fence. Plywood was used to cover the adult trap area.

## Physical Observations

Crews monitored water temperatures, water levels, and weather daily. Crews recorded temperature to the nearest degree $\left(1^{\circ} \mathrm{C}\right)$ using a maximum-minimum thermometer and water level using staff gauges calibrated to the nearest centimeter ( 0.01 m ). A total of three staff gauges were used; two were located within 50 m of the trapping site (one upstream, one downstream of the fence) and one approximately 1 km upstream of the fence. Precipitation was recorded on a scale of zero to five with zero representing no precipitation and five being heavy precipitation.

## Fish Enumerations

Daily numbers of coho smolts captured at the fence were obtained from automatic counters on coded-wire tagging machines or by manual counts. The number of fence mortalities
was added to the total count. Coho juveniles with standard lengths greater than or equal to 70 mm were identified as smolts. Coho smaller than 70 mm tended to be dark with distinct parr marks and lacked the silver colouration typical of smolts. Therefore, this group consisted of presmolts and fry. All coho pre-smolts and fry, and non-coho species were counted and released downstream of the fence during sorting. Upstream migrating juveniles caught in the adult traps were counted and released upstream.

## Biosampling

A random sample of up to 25 smolts (i.e., coho greater than or equal to 70 mm ) were obtained from each day's catch. These smolts were anaesthetized and measured for fork length and weighed using an electronic scale ( 0.1 g ). Scale sampling followed the stratified method of Ketchen, described by Ricker (1975); age sample data (column X on Table 1) included nonrandom samples, and length sample data (column Y on Table 1) and the calculated age representation was based on random sampling. Crews attempted to collect at least 10 scale samples from each 5 mm size class of coho for the study period. Smolts from under-represented size classes were selected to supplement random samples. Mean length and weight data was determined by multiplying the mean length and weight data for each 5 mm bin class by the total number of length and weight samples in that bin class (factor) to come up with a weighted mean length and weight for that bin class. The average length and weight for all sampled fish was determined by summing all the weighted length and weight measurements and dividing by the overall sum of the factors. Scale samples were interpreted by the Fisheries and Oceans Canada Scale Lab, Nanaimo, BC. Secondary quality control checks were performed to ensure a reliable age designation. Scale ages are reported in Gilbert-Rich notation where freshwater age-2 coho (i.e., having survived two winters from egg deposition) have a single freshwater annulus.

## Coded-wire Tagging

Coded-wire tagging at Zolzap Creek was performed using a Mark IV tagging machine (Northwest Marine Technology Ltd. Shaw Island, WA). Smolts were anaesthetized in a MS222 bath prior to tagging. All tagged fish were adipose fin-clipped (AFC). The numbers of coho smolts tagged with each tag code and the number of smolts untagged were recorded. All tagged smolts were placed in a holding box in the stream and allowed to recover from the tagging operation before release.

Tag retention tests were conducted for each tag code. A sample of tagged coho smolts (minimum of 200 smolts) were retained in a holding box from 24 h to 72 h . Following the holding period, smolts were lightly anaesthetized and checked for the presence of a coded-wire tag using the quality control device ( QCD ) from the coded-wire tagging machine. Coho smolts not possessing a tag were checked a second time. The total number of tags detected for each tag group and the total number of fish tested was recorded.

## RESULTS

## Physical Observations

Water temperatures during the smolt migration period at Zolzap Creek ranged from a minimum of $3^{\circ} \mathrm{C}$ in early May to a maximum of $9^{\circ} \mathrm{C}$ in mid-June (Figure 3A). Water level at gauge $2(50 \mathrm{~m}$ upstream of the fence) remained steady at a gauge height of approximately 0.3 m from the beginning of monitoring on 29 April until 19 May. Water level rose steadily to a level of 0.8 m on 23 May and then rose rapidly to a level of 1.4 m on the 29 May. The fence was flooded out for four days (15-18 June) with water levels declining afterwards until the end of the spring monitoring period. High water levels in Zolzap Creek occur when the Nass mainstem flow rises causing water to back-up into the creek. Water flow in Zolzap Creek declines to very low velocities during these flooding events.

## Fish Enumerations

The Zolzap Creek juvenile counting fence was operated from 29 April to 26 June 2002. The fence was topped for a four day period from 15-18 June and then operated without further interruptions until the end of the spring monitoring period. Approximately 25 to 30 baited gee traps were used to supplement catches at the fence during periods of high water and low smolt movement.

Coho Smolts: A total of 15,001 coho smolts were counted at the fence and included gee trap catches (Table 2). The maximum daily number of smolts captured at the fence was 1,833 and occurred on 21 May (Table A-1, Figure 4). There were a total of 2,891 fry and pre-smolt coho counted and released during trapping operations and 25 mortalities (Table A-1).

Non-coho Species: Lampreys (larvae and young adults) were caught in the largest numbers, followed by juvenile Dolly Varden, juvenile cutthroat, and juvenile steelhead (Table 3, Table B-1).

## Biosampling: Length, Weight, and Age

The mean fork length of age- 2 smolts was 98.3 mm and the mean weight was 9.7 g (Table 1). Age-3 smolts averaged 109.7 mm and 13.1 g . The length-frequency distribution showed substantial overlap between age-2 and age-3 coho (Figure 5). Age-2 smolts were most numerous in the 95-100 mm length class and age-3 smolts were most numerous in the 100-110 mm length class. Age-3 coho smolts were significantly larger than age- 2 smolts ( $\mathrm{t}-\mathrm{test}, \mathrm{p}<$ 0.05 ). Overall, coho smolts averaged 101.5 mm in length. The calculated freshwater age structure of coho smolts was $69.6 \%$ age-2 and $30.4 \%$ age- 3 (Table 1).

## Coded-wire Tagging

Mean tag retention was $98.7 \%$ for tag code 28-01-10, and $99.0 \%$ for tag code 28-01-11 (Table 4). Crews conducted 10 tests for tag code 28-01-10 for a total of 1,972 samples with 25 tag losses, and 3 tests for tag code 28-01-11 for a total of 600 samples with 6 tag losses.

Releases of adipose fin-clipped coho totalled 12,412 (Table 5; Table C-1). Crews recorded 80 mortalities associated with the tagging process. The total number of coho smolts released with coded-wire tags was 12,318 . Approximately $4 \%$ (468) of the captured coho smolts were released untagged during the study period and thus the mark rate of coho smolts released was 1.05 (Table 5). The total number of smolts released was 12,880 .

## ADULT COHO STUDIES

## METHODS

## Population Estimates

An aluminum conduit fence anchored to a crib-type sill was constructed at Zolzap Creek. All salmonids caught at the fence were counted and classified by sex. Sex was distinguished on the basis of length and body morphology. Previous studies at Zolzap Creek (Nass 1996b, 1996c, 1997a, 1997b, Nass 2001, Nass and Frith 2001, Baxter et al. 2001, Baxter and Stephens 2002, Baxter and Stephens 2002a, Baxter and Stephens 2002b) have shown an absence of jacks in the escapement, and therefore all males were classified as adults. "Jack panels" consisting of 1" wire mesh were used to prevent the passage of small coho through the fence and were used whenever water levels and debris permitted. Each coho was tagged on the operculum with a uniquely numbered Ketchum kurl-lock tag and measured for length. During handling, fish were examined for fin clips or tags that would be associated with coded-wire tagging or markrecapture studies taking place on the Nass River. All captured fish were released upstream of the fence.

Adult coho abundance downstream of the fence was assessed later in the migration period due to the lack of fish movement past the fence. Delayed migration was the result of persistent low water conditions in Zolzap Creek in the later fall period. During these periods of delayed fish movement, angling was conducted approximately 1 km downstream of the fence in Zolzap Slough to determine relative coho abundance. Live coho were recaptured in upstream surveys and checked for operculum tags. Carcasses were recovered on the fence and during upstream surveys. In 2002, carcasses were recovered primarily in the lower 5 km of the creek.

## Biosampling

All live coho captured at the fence were measured for postorbital-hypural length and examined for fin clips and sex. Data recorded from coho captured at the fence were used to calculate sex ratios and mean-length by sex. Crews attempted to sample at least 25 coho a day for scales ( 5 scales per fish). Scale samples were sent to the Fisheries and Oceans Canada scale
lab, Nanaimo, BC for age determination. Secondary quality control checks were performed at the scale lab to ensure reliability of the age designations. Scale ages are reported in Gilbert-Rich notation where freshwater age-2 coho (i.e., having survived two winters from egg deposition) have a single freshwater annulus.

Adult returns (calculated by escapement method) and smolt production, by CWT and total populations, were calculated for each brood year where data was available. Smolt output and adult escapement were apportioned between brood years (back-calculated) using the age structure observed in the respective yearly migrations. The sum of freshwater age-2, age-3, and age-4 individuals equals total production for a given brood year. Age composition for smolts and adults by brood year were calculated based on the estimated production. Total survival by brood year was calculated as the age specific adult return divided by the respective smolt production. Smolt-to-spawner recruitment for each brood year was calculated as the number of smolts produced divided by the number of adults in the escapement, by brood year. Similarly, the recruit-to-spawner ratio for each brood year was calculated as the number of adults produced divided by the number of adults in the escapement, by brood year.

## Coded-wire Tag Recoveries

Coded-wire-tagged smolts were adipose fin-clipped prior to release. Coho smolts at Zolzap Creek were coded-wire tagged in the spring of 2001 (Baxter and Stephens 2002b) during out-migration.

Escapement: Crews examined all coho captured at the fence for the presence or absence of the adipose fin. The contribution and survival of AFC coho to the escapement was determined using methods presented in Bocking et al. (1992) and modified in Nass (1997a). Coded-wire tagged heads were collected from fish captured at the Nass River fishwheels, fish recovered in the native angling fishery below and above the fence, and from carcass recoveries.

Commercial and Sport Harvests: Commercial and sport catches of CWT fish are monitored by the Fisheries and Oceans Canada and various US agencies and compiled in the Mark Recovery Program (MRP) and in the ADF\&G mark tag and age lab online searchable database. Data on CWT releases and recaptures are used to estimate the number of fish from a particular stock that have been harvested in the commercial and sport fishery, as well as determining the spatial and temporal distribution of harvests (Kuhn et al. 1988, Nass 1997a). The estimates include catch (observed catch corrected for sampling effort), expanded catch (estimated catch corrected for unmarked fish), exploitation rate (proportion of CWT coho caught in the fishery), and total return (expanded catch plus escapement).

Geographic Distribution of Harvest: Coded-wire tagged fish in the commercial catch are recorded by Canadian and US fishery Statistical Areas. To estimate number of recoveries for each Canadian area, the observed CWT catch was expanded by the mean catch-sampling ratio observed in the Catch Region (e.g., Northern Troll = Stat. Areas 1, 3, 4, and 6). Similarly, US troll catch was expanded using the catch sampling ratio by quadrant (e.g., northwest) and the net catch sampling ratios, by district.

## RESULTS

## Physical Observations

During the period that the adult fence was operational, water temperatures ranged from a maximum of $10^{\circ} \mathrm{C}$ in early September to a minimum of $8^{\circ} \mathrm{C}$ in early-October (Figure 3B). Water level ranged from 0.3 m during base flows to 1.2 m during freshets (Figure 3B).

## Adult enumerations

The fence was operated continuously from 21 August to 4 October. A rain on snow event that occurred on the 5 October resulted in extreme flow conditions and caused a complete failure of the adult fence. A total of 1,918 adult coho salmon were counted at the fence including 6 coho released untagged (Table 6). Of these, 1,818 adults (adjusted for tag loss) were operculum tagged and released upstream. Maximum daily migration past the fence was 399 adults on 19 September (Table D-1) (Figure 6).

Coho capture surveys were conducted below the fence on 2, 3, 5, 6 and 7 September. A total of 39 coho were caught during these surveys. All coho caught were sexed, opercular tagged, checked for AFC's and then transported by boat above the fence.

For non-coho species captured at the fence, pink salmon had the greatest abundance (17), followed by cutthroat (12), chum salmon (5), and steelhead (4). Dolly Varden (3) and sockeye (1) were also captured at the fence (Table 3). Chum, pink, and sockeye were caught in their greatest numbers in early-mid September. Cutthroat and Dolly Varden were mainly caught in mid-late September. The number of chum, sockeye and pink caught in 2002 were much lower than in 2001 and well below the 1992-2001 averages (44, 13 and 87 respectively). No population estimates were derived for non-coho species.

## Mark-recapture Estimates

Crews examined a total of 653 adult coho carcasses collected on the fence, and in twentythree upstream surveys. Surveys were conducted upstream of the fence from 11 October to 3 December at three access locations along the creek. Upstream surveys were conducted on 15 , 24, and 28 October, 6, 12, 19 and 26 November and 3 December at Goat Creek (a tributary); 11, 16, 21, 29 October, 13, 18 and 25 November and 2 December at upper Zolzap Creek. Of the 653 adult coho examined, 367 were tagged, 269 were untagged and 17 had lost their tags, which resulted in a Peterson population estimate of 3,233 adults ( 2,919 to 3,$580 ; 95 \% \mathrm{CI}$ ) escaping to Zolzap Creek in 2002 (Table 6). An undetermined number of coho were observed spawning below the fence and in the Zolzap Slough area, so our estimate of 3,233 adult coho is likely underestimated.

## Biosampling - Age and Length

A total of 216 coho were sampled for scales, of which 183 were successfully aged (Table 7). Unaged samples included marine regenerates. Adult males and females had different age compositions which averaged $71.1 \%$ and $78.0 \%$ freshwater age-2, and $28.9 \%$ and $22.0 \%$ freshwater age- 3 respectively. The overall age composition was $74.9 \%$ age- 2 , and $25.1 \%$ age- 3 . All aged scales were recorded as marine age-1 (i.e., having 1 marine annulus).

Mean lengths of adult males and females were 46.9 cm ( $\mathrm{n}=753, \mathrm{SD}=7.9$ ) and 49.3 cm ( $\mathrm{n}=1,111, \mathrm{SD}=6.2$ ), respectively. Adult male coho were widely distributed over the range of 30 to 71 cm with a mode of 52 cm (Figure 7). Female coho also had a mode of 52 cm with a range of 26 to 65 cm . For coho sexed during processing, adult females captured at the fence ( $\mathrm{n}=1,111$ ) were more abundant than males ( $\mathrm{n}=753$ ).

## Coded-wire Tag Recoveries

Escapement: Crews examined 1,905 adult coho at the fence for fin clips of which 883 were AFC ( $46.4 \%$; Table 8). An estimated 1,499 adipose clipped adult coho returned to Zolzap Creek in 2002. An undetermined number of AFC coho spawned below the fence and in the Zolzap slough area. Smolt to spawner survival (i.e., includes natural and harvest mortality) for adult coho was estimated at $6.7 \%$.

Eleven (11) CWT heads were collected at Zolzap Creek. Of these recoveries, 4 were from the native angling fishery below the fence and 7 were from carcass recoveries. In addition, 6 coho with adipose clips were recovered at the Nass River fishwheels. All of the CWT recoveries from Zolzap Creek were from the 2001 release at Zolzap Creek (codes 28-01-06 and 28-01-07). Of the 6 fishwheel CWT recoveries, 2 were from the 2001 release at Zolzap Creek (codes 28-01-06, 28-01-07), 1 was from the 2000 release at Zolzap Creek (code 28-01-05), and 3 were No-Pin.

Commercial and Sport Harvests: Total observed Zolzap Creek coho CWT recoveries were 7 and 102 for Canadian and US (Alaska) fisheries, respectively (Table 9). Observed sport recoveries totalled 0 for the Canadian fisheries and 4 for the Alaskan fishery. All CWT recoveries were from the 2001 release year. US troll and net catch to sample ratios were 2.7 and 4.9, respectively (Table 9). Estimated Zolzap Creek CWT coho catches were 57 (15\%) and 312 ( $85 \%$ ) for Canadian and US fisheries, respectively, and the Nisga'a food fishery at Zolzap Creek harvested an observed 4 CWT coho (Table 9).

Expanded Canadian and US catches were 78 and 391, respectively, for a total of 469 using the CWT mark ratio at release (i.e., MRP method) (Table 10). Expanded Canadian and US catches were 124 and 673, respectively, for a total of 797 using the adipose clip ratio at recovery (i.e., escapement method). Estimated total adult return for Zolzap Creek coho was 2,264 and 4,030 using the MRP and escapement methods, respectively (Table 10).

Of the total commercial catch of Zolzap Creek coho, Canadian fisheries accounted for $16.1 \%$ and the US accounted for $83.9 \%$ of the total commercial catch of Zolzap Creek coho (Table 11). US troll and net fisheries accounted for $76.2 \%$ and $23.8 \%$ of the total US catch, respectively. Canadian troll and net fisheries accounted for $15.6 \%$ and $0.6 \%$ of the total Canadian catch. Commercial harvest of Zolzap Creek coho occurred over a wide area ranging from Canadian Statistical Area 5 to the US Northern Outside Statistical Area in Alaska (Figure 8). US harvests were largest in the Southern Inside Statistical Area for the net fishery (15.0\%) and the Central Outside Statistical Area for the troll fishery (29.6\%; Table 11).

Total exploitation rate (Canadian and US combined) on Zolzap Creek coho in 2002 was $19.9 \%$ (Table 12). Total Canadian exploitation rate was $3.3 \%$ ( $3.0 \%$ troll, $0.1 \%$ net, and $0.2 \%$ terminal harvest by Nisga'a) and total US exploitation rate was $16.6 \%$ ( $11.5 \%$ troll, $4.4 \%$ net, and $0.7 \%$ sport). Total survival based on CWT returns was $8.4 \%$ (Table 12).

## DISCUSSION

Over the past ten years of monitoring, the average number of smolts estimated leaving Zolzap Creek was 28,318 (Table 12). For the same time period, the average age composition of the smolt population was $65.7 \%$ age-2, $33.6 \%$ age- 3 , and $0.7 \%$ age- 4 (Table 13).

Adult coho enumerated at the fence in $2002(1,918)$ accounted for $59.3 \%$ of the Peterson population estimate $(3,233)$. Therefore, approximately 1,315 adults entered Zolzap Creek during the period in which the fence was not operational. An undetermined number of coho were observed spawning below the fence and in Zolzap Slough. The observed native fishery harvested 7 coho below the fence of which 4 were CWT. The observed sport fishery harvested 3 coho below the fence of which 0 were CWT. Average escapement estimates for 1992-2001 was 1,395 (Table 12).

Data from 1992 to 2001 have indicated that there are no jacks in the Zolzap Creek escapement (Nass 1996b, 1996c, 1997a, 1997b, 2001, Nass and Frith 2001, Baxter et al. 2001, Baxter and Stephens 2002, Baxter and Stephens 2002a, Baxter and Stephens 2002b). In 2002, CWT and scale ageing data have confirmed again the absence of jacks in the population. There were 11 heads taken at Zolzap Creek for CWT sampling from coho measured between 42 and 58 cm (post-orbital-hypural) and all were found to be from 2001 releases. A post-orbital-hypural length of 35 cm has been used in previous studies at other BC streams to designate jacks in the escapement and is based on CWT analysis. Both the CWT analysis and scale ageing show that coho less than 42 cm from Zolzap Creek in 2002 were marine age-1.

The Department of Fisheries and Oceans, Canada, operates a juvenile and adult fence site at Lachmach River, BC which is used as a Northern BC wild coho indicator stock. Exploitation rates for Lachmach coho have ranged from $21.8 \%$ to $70 \%$ for the 1994-2001 period (Holtby et al 1999, Barry Finnegan, PBS, Nanaimo, pers. comm.). These exploitation rates are very similar to Zolzap exploitation rates for the 1994-1999 time period (Figure 9). Total survival for Lachmach coho has ranged from $5.5 \%$ (1997) to $17.4 \%$ (1994) and has been consistently higher than Zolzap Creek survivals (Figure 10).

In Alaska, comprehensive information exists for several southeast stocks, including Hugh Smith Lake (Southern Inside Statistical Area, see Figure 8), which has been monitored since 1982. Preliminary data for the 2002 return suggests exploitation rates of $0 \%$ Canadian and $37.4 \%$ US ( $37.4 \%$ total; Leon Shaul, Alaska Dept. of Fish and Game, Douglas, AK, pers. comm.). Southeast Alaska and Canadian fisheries accounted for approximately $100 \%$ and $0 \%$ of the commercial catch of Hugh Smith coho, respectively. The total exploitation rate on Hugh Smith coho (37.4\%) was almost double as compared to exploitation rates on Zolzap Creek coho (19.4\%) in 2002. Preliminary CWT data for the 2002 return of Hugh Smith coho suggest a survival rate of $14.4 \%$ which is higher than for Zolzap Creek coho at $8.4 \%$. Hugh Smith coho have had substantially higher survivals (range $6.6 \%$ to 19.4\%) compared to Zolzap coho (range $2.4 \%$ to $8.9 \%$ ) in the past nine years.

Zolzap Creek CWT coho have been subjected to total exploitation rates between 19.4\% and $72.3 \%$ and have had smolt-adult survival rates between $2.1 \%$ and $8.9 \%$ over the period 1992 to 2002 (Table 12, Figs. 9, 10). 2002 survivals were the second highest recorded since 1992. Canadian fisheries have had exploitation rates between $0 \%$ and $21.4 \%$ on Zolzap CWT coho, while US fisheries ranged between $17.0 \%$ and $54.8 \%$ (Figure 11). Of the total catch of Zolzap Creek coho, Canadian fisheries have averaged $17.7 \%$ and the US has averaged $82.3 \%$, over ten years (Table 12).

Total smolt production by brood year averaged 28,066 (1990-1998) and was composed primarily of freshwater age-2 fish ( $66.7 \%$; Table 13). Adult production by brood year averaged 3,082 (1990-1997) and was $56.7 \%$ age-2 fish. Age composition at return was substantially different from that observed in the respective smolt populations and varied widely. Freshwater age- 4 fish were absent from all adult escapements with the exception of the 1995 brood year. Total smolt-adult return by brood year of all Zolzap coho (unmarked + CWT) averaged 11.6\% (1990-1997; Table 13). Total smolt-adult return of Zolzap CWT coho was substantially lower at $4.8 \%$. Higher survival for all coho compared to CWT coho is likely due to a significant number of unmarked smolts leaving Zolzap during non-operational periods (Nass 1996c). The effects of these conditions are evident from the historical data which shows the AFC at release has been roughly three times that of the AFC rate at return for the period 1993-1999 at Zolzap Creek (Table 8). Therefore, by using only CWT fish, the uncertainty around the number of fish released is eliminated and produces a more accurate estimate of survival for Zolzap coho smolts.

Estimates of total survival and exploitation are based on the assumption that all CWT coho are recovered in fisheries or on the spawning grounds. At Zolzap Creek, it is possible that the escapement of AFC coho is underestimated due to straying. Coho are known to spawn downstream of Zolzap Creek in Zolzap Slough (a side channel to the Nass River) where some CWT coho may return. In addition, a total of six adipose clipped coho were recovered in the fishwheels above Zolzap Creek in 2002 ( 2 were from the 2001 release at Zolzap Creek, 1 was from the 2000 release at Zolzap Creek and 3 were No-Pin) which tends to confirm our theory of straying. Straying would affect Zolzap Creek survival and exploitation estimates by underestimating survival and overestimating exploitation rates.

Zolzap Creek coho survivals may also be lower than Lachmach and Hugh Smith coho due to predator/prey interactions, with Zolzap Creek coho being more vulnerable to predation during their outmigration. Hugh Smith and Lachmach are both coastal systems and empty directly into marine waters, whereas Zolzap Creek empties into the Nass River. Zolzap Creek smolts must migrate approximately 33 km through Riverine habitat until they reach the ocean and are therefore more susceptible to predation along the way.

Persistent low water conditions at Zolzap Creek in the fall result in coho holding below the fence in Zolzap Slough until water levels rise. During certain low water years, this may result in coho spawning in the Slough area or pulsing through after the fence is demobilized. During these times, the run timing of the returning adult coho may be more an artifact of water levels rather than natural run timing. It is recommended that during subsequent years, the fence be run longer into the fall and increased effort be apportioned to upstream surveys to ensure a complete census of returning coho.

The number of smolts per spawner was 42.7 for the 1998 brood year. This value is conservative as the number of smolts released was likely underestimated. The number of recruits per spawner was 4.6 for the 1998 brood year (Table 13).

## ACKNOWLEDGMENTS

The cooperation of many people was essential in meeting the objectives of this study. Special thanks go to Leonard Squires for monitoring all aspects of operations as crew supervisor. Simon Haldane, Vincent Johnson, Dan Gonu, Leonard Guno, Kirby Guno, Pamala Wright, and Lawrence Stephens assisted in constructing and operating the fence. Bob Bocking provided technical support and reviewed the manuscript. Doug Herriot and Brenda Adkins of the Department of Fisheries and Oceans provided the CWT catch data from the Mark Recovery Program. Barry Finnegan (PBS, Nanaimo) and Joel Sawada (DFO, Prince Rupert) provided the Lachmach data. Thanks also to Leon Shaul (ADF\&G) for providing Hugh Smith data. Robin Tamasi provided mapping support. Funding for this project was provided by the Canadian Government and Nisga'a Lisims Government as part of the Nisga'a Final Agreement.

| Totals | 1,918 | 1,906 |

[^8]
[^0]:    ${ }^{1} 9768$ Second St., Sidney, BC V8L 3 Y8
    ${ }^{2}$ PO Box 228, New Aiyansh, BC V0J 1A0

[^1]:    ${ }^{\text {a }}$ No. tagged (corrected for tag loss) $=$ No. released AFC - (No. released AFC $*$ No. lost tags / No. sampled); see Table 4.
    ${ }^{c}$ No. released untagged $=$ the number of unmarked fish released which belong to the same group as the tagged and AFC only fish. ${ }^{\mathrm{d}}$ Total release $=$ No. tagged + AFC only + untagged
    ${ }^{\mathrm{e}} \mathrm{CWT}$ mark rate $=$ Total release $/$ No. tagged

[^2]:    ${ }^{a}$ Includes 1,879 adult coho examined at fence and 39 adult coho angled and tagged below fence and subsequently released above fence.
    ${ }^{b}$ Adjusted for tag loss.

[^3]:    ${ }^{\text {a }}$ smolt releases of the previous migration year; an unknown number of additional unclipped releases were likely.

[^4]:    ${ }^{\text {a }}$ Observed CWT = CWT's recovered from the commercial and sport catch
    ${ }^{\mathrm{b}}$ Cumulative catch-sample ratio $=$ total coho catch $/$ total coho sampled
    ${ }^{\text {c }}$ Estimated CWT = observed CWT catch ${ }^{*}$ catch sampling ratio
    ${ }^{d}$ observed harvest
    ${ }^{e}$ Estimated CWT's (adipose clips corrected for tag loss at return) including those below the fence, and at the fishwheels; see Table 8

[^5]:    ${ }^{\text {a }}$ Number smolts released with tags (corrected for tag loss), Nass and Frith 1997.
    ${ }^{6}$ Mark rate at release ( $=$ No. released / No. marked) for smolts and Total 1 (MRP method), and mark rate at return for total 2 (Escapement method).
    ${ }^{c}$ Expanded catch $=$ EST $*$ mark rate at release
    ${ }^{d}$ Total returm $=$ expanded catch + escapement
    ${ }^{\text {e }}$ Total 1 expanded catch is calculated using the total mark rate at release and the total estimated catch for all tag codes (Table 9).
    ${ }^{\mathrm{f}}$ Total 2 expanded catch is calculated using the total adipose clip rate at recovery and the total estimated catch for all tag codes (Table 9).

[^6]:    ${ }^{\text {a }}$ includes respective sub-areas

[^7]:    ${ }^{2}(-)$ Incomplete data for 1999 , to be completed with data from subsequent returns. baverage for "Total" includes years for which complete production data is available. ' Age conposition of adult escapement return for brood year.

[^8]:    ${ }^{\text {a }}$ Includes 1,879 adult coho examined at fence and 39 adult coho angled and tagged below fence and subsequently released above fence.
