1.0 INTRODUCTION

A fisheries survey of tributary streams to Babine Lake was conducted between late July and September 1988. The study was designed to assess recruitment of rainbow trout from Babine tributaries in a program sponsored by the Habitat Conservation Fund, Ministry of Environment. A total of 57 streams were sampled during the course of the study and the results summarizing rainbow recruitment to Babine Lake are presented in Bustard (1989). In addition to collecting information describing juvenile rainbow trout use of these tributaries, juvenile coho were found to be present in the lower reaches of many of the tributaries examined.

This report summarizes the coho salmon results and provides a rough estimate of the production of coho salmon juveniles in streams tributary to Babine Lake. It was prepared at the request of Tom Pendray of the Habitat Management Section of the Department of Fisheries and Oceans, Prince Rupert.

1.1 Background

Babine Lake is the largest natural lake entirely within the province of British Columbia. It is a long (150 km) narrow lake located on the Central Interior Plateau and forms one of the major drainage basins in the Skeena River system (Figure 1). The lake lies at 55 N latitude, 123 W longitude and is at an elevation of 708 m. It has an area of 490 km^2 , mean depth of 55 m and a maximum depth of 186 m (Johnson 1965). Information describing the limnology of Babine Lake is reviewed in Levy and Hall (1985).

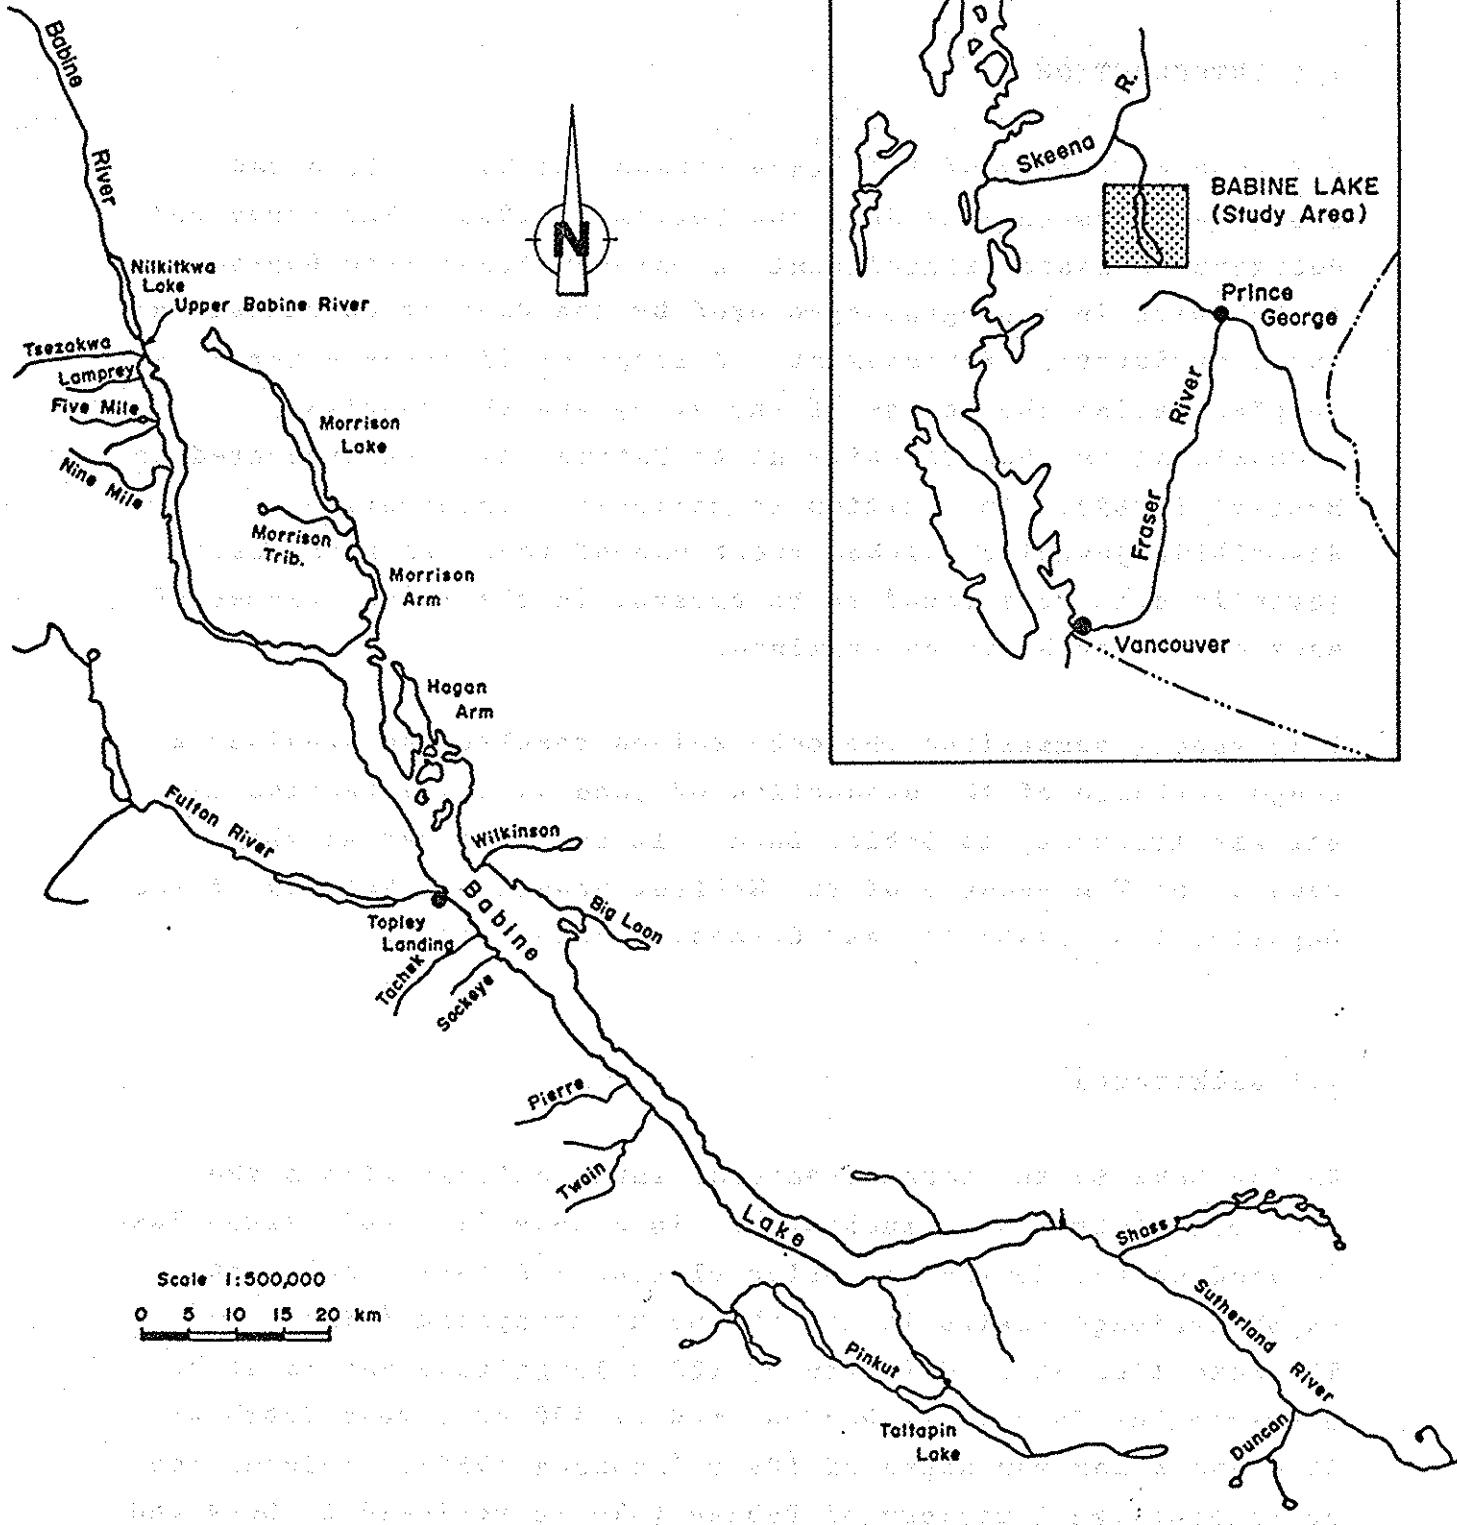

Figure 1. Location of Babine Lake and main tributaries.

The Babine Lake watershed encompasses an area of approximately 10,000 km². The watershed contains four main sub-basins, including the Fulton, Pinkut, Sutherland and Morrison watersheds which drain 21.1, 13.3, 13.1 and 6.8% of the Babine watershed respectively. The rest of the Babine watershed boundary (46.6%) is very close to the lake and numerous small creeks, many with intermittent flow, discharge directly into Babine Lake.

1.2 Babine Lake Fisheries

Babine Lake is well known for its large run of sockeye salmon that can exceed 2 million fish in some years and presently accounts for up to 90% of the Skeena River sockeye production (Levy and Hall 1985). At least 16 tributaries to Babine Lake are used by spawning sockeye (Hancock et al. 1983). As well, some shore spawning occurs along the lake. A scattered incidence of pink and chinook salmon spawning has been reported in systems such as the Fulton River (Hancock et al. 1983).

A significant population of coho salmon spawn in the upper Babine River between Babine Lake and Nilkitkwa Lake. Estimates based on the recovery of fish tagged at the fence below Nilkitkwa Lake indicate a mean escapement of just over 4000 fish to this section of the river from 1975 to 1988 (Table 1). A smaller number of coho also spawn in the Babine River downstream of Nilkitkwa Lake in the vicinity of the counting fence.

Coho salmon also spawn in Babine Lake inlet tributaries, although the extent and distribution of coho is poorly documented since they spawn late in the season after the sockeye counts are complete. A review of historical records (Hancock et al. 1983) indicates that coho spawning has been documented in

nine tributary streams to Babine Lake (Figure 2). The two most important tributaries identified are the Fulton River and Pinkut Creek (Table 1), probably reflecting the presence of the counting fences and staff present on these systems during the spawning period. Recent coho escapements in the Fulton River range from 300-500 fish while Pinkut escapements are lower and range from 12-300 fish (Table 1). Escapement estimates for other tributaries indicate small historical populations particularly in Pierre, Morrison and Shass (Sutherland River tributary) creeks. Estimates prior to 1975 suggest that coho escapements were considerably higher than the more recent escapement estimates presented in Table 1. For example, Fulton River coho escapements averaged over 800 fish for the 25 years prior to 1975. Coho counts at the Babine fence have declined from over 10,000 spawners in the mid-sixties to approximately 3000 fish in the 1980's (data on file, DFO, Smithers).

1989		300	150

Limited tributary surveys have been conducted prior to the 1988 study on portions of the Babine watershed. For example, some work had been conducted in the Pinkut Creek watershed, mostly above the barrier at 2.3 km (Carmichael 1977). As well, Graham et al.(1976) provide some aerial habitat descriptions of 14 sockeye spawning streams, and additional information on these main salmon streams is presented in Hancock et al. (1983). Tributary fish sampling was conducted in the Morrison Arm area as part of a program for folio development for logging in this area (Hatlevik 1981). As well, some juvenile trapping data has been collected at the lower end of Morrison Creek (Orr 1984).

The Department of Fisheries and Oceans has been assessing coho use of several inlet tributaries to Babine Lake during the past several years as part of a program to assess the exploitation rate of Babine Lake coho in the commercial fishery. A program initiated in 1988 involving egg-takes at the Fulton and Pinkut fences and releasing fed-fry is underway on the Fulton River and Pinkut Creek and is continuing during 1990. As part of this program, electroshocking has been conducted on the Fulton and lower Sutherland rivers and Morrison Creek (Dr. Mason, DFO, personal communication).

2.0 METHODS

Preliminary data compilation and map (1:50,000) and air photo interpretation was undertaken in June and July. All tributary streams were broken into reaches and possible barriers located. The juvenile fish sampling was undertaken by a crew of two during late July, August and September. Sites were mainly located in stream sections accessible to fish from Babine Lake, although

some sites were located upstream of known barriers. Tributaries to Nilkitkwa Lake were not examined.

Access to sites was usually by vehicle where road access existed and by boat to the mouth of the streams that did not have road access. In these situations, sampling was usually restricted to the lower 1 km of the stream. The limited helicopter time available for this study was concentrated on otherwise inaccessible sites in the Sutherland River and several smaller streams at the south end of Babine Lake.

Representative sample sites 10-30 m in length were located in 57 streams. A minimum of one site was established per stream, while up to 11 sites were established in the Sutherland River and its tributaries. Emphasis was placed on the larger systems due to their more extensive and diverse habitat. In all, 87 sample sites were established. Nine additional streams that were visited were considered to have low potential and were not sampled further.

Tributary sites were enclosed with stopnets and electrofished. Population estimates were derived using a two-pass removal technique described by Seber and LeCren (1967). Main channel sites on larger systems such as the Fulton, Pinkut, lower Sutherland and Tsezakwa Creek were enclosed using a 30 m seine around rebar positioned prior to sampling. This technique sampled most of the usable coho habitat. Estimates were doubled on these larger systems to account for the two sides of the stream.

All fish captured were anaesthetized, counted and returned to the stream after sampling. A sample of 30 fish of each species was measured to the nearest millimeter. A representative range of

sizes of each species of fish was weighed and used in calculating biomass estimates. Scales were retained from 9 coho salmon juveniles from Tsezakwa Creek for age determinations. This information, along with length-frequency data was used to separate fry and yearling coho for the systems.

Sample site areas were calculated from a single length and a series of width measurements at each site. As well, water depths, substrate, cover characteristics, pool-riffle ratios, water temperature and estimated flow were recorded at each site.

Reach lengths were calculated from 1:50,000 scale maps and estimates of productivity were made using reach length and the number of fish per meter of stream length. Some judgment was used in applying catch information to stream reaches that apparently contribute to Babine Lake coho recruitment but were not sampled due to access difficulties.

For simplification, streams shown in Figure 2 are numbered from 1 to 36 and their corresponding watershed code and name (if they have one) is given. Some of the names given in this report to previously unnamed tributary streams are not gazetted.

3.0 RESULTS

A total of 3073 fish were estimated within the sample sites for all of the Babine Lake tributaries (57 streams) that were electrofished (Table 2). Juvenile coho comprised 18.4% of the total sample. Nearly 60% of the fish captured in the tributary streams were rainbow trout. Other species included prickly sculpins (12.1%), longnose dace (4.6%), and Dolly Varden char (2.8%). The remaining 3% of the catch consisted of squawfish, mountain whitefish, redside shiners, longnose suckers, burbot and a single brassy minnow captured in the mid-reaches of the Sutherland River.

Juvenile coho were present in 36 of the 57 streams (Figure 2). Sympatric populations of coho and rainbow occurred in 27 streams. The frequency of occurrence of all species in the sampled streams is shown in Table 2.

3.1 Juvenile Coho Life History Characteristics

Most juvenile coho captured were age 0+ (75%), with age 1+ comprising nearly 25% of the sample. Scale analysis of several larger coho (110-115 mm) captured in July in Tsezakwa Creek indicated that these fish were age 2+.

A summary of the length frequency distribution of 299 juvenile coho from 18 tributaries sampled during August is combined and presented in Figure 3. Fry averaged 62.3 mm fork length ($n=192$) and yearlings averaged 84.0 mm ($n=107$). Based on the aging of a small sample of scales and the length frequency information, fish greater than 76 mm were assumed to be yearlings. The actual break-off point between fry and yearling presumably varied for each system. For example, the mean fry sizes from a

3.2 Overall Tributary Production Estimates

The 36 streams that possessed coho salmon juveniles comprised approximately 62 km of accessible stream that could produce juvenile coho (Table 4). Most of the coho tributaries of Babine Lake are accessible for less than 5 km, and many for only 1 km or less.

The Sutherland River and tributaries could provide up to an additional 78 km of accessible stream. However, only a single juvenile coho was captured at 8 sample sites in this system. This is surprising since the lower Sutherland is comprised of extensive low velocity sections with abundant debris cover and appears ideal for coho rearing. The Sutherland is accessible during the fall to at least Duncan Creek based on the presence of kokanee this far upstream during some years. Historical records indicate that coho spawn in lower Shass Creek (Hancock et al. 1983), and Bob Lamont (DFO, Pinkut, personal communication) indicates that up to 500 coho spawned in the Sutherland in the Shass Creek area during 1987 indicating that substantial fry recruitment should have been available to the downstream areas. Only a single area was sampled downstream of Shass Creek. However, Dr. Mason (DFO, personal communication) indicates that he also did not find any juvenile coho use of the lower Sutherland when he electroshocked sites downstream of Shass Creek.

It should be noted that the upper point of access on many of the streams is approximate and is based on a combination of air photo and map interpretation, ground observations (often by fishery officers conducting spawner enumeration surveys), and aerial reconnaissance (Graham et al. 1976), and the present study. In some instances, where no known barriers are present,

See Appendix 1 for a summary of all streams.

the upper extent of access has been estimated based on stream gradient and size. As well, tributary streams to Nilkitkwa Lake (Figure 1) may contribute substantially to coho production since they are based downstream from extensive spawning areas in the upper Babine River, but no rearing estimates for this area are available.

Juvenile coho rearing estimates from the tributary streams totalled 31,068 fry and 10,794 yearlings (Table 4). The highest population estimates were in Sockeye, Tributary 2500, Hazelwood, and Lamprey creeks (Table 4 and Figure 2). These four systems together accounted for nearly 60% of the coho fry numbers. Highest yearling numbers were found in Tsezakwa Creek. The absence of coho fry in this system suggests that coho spawners may only use this system during some years.

The methods used in arriving at the estimates in Table 4 are outlined in Appendix 1. A number of qualifying comments are appropriate to outline some of the limitations of these estimates. Firstly, the sample sites are small relative to the overall system lengths, and considerable error can be involved in extrapolating the results of catches from one short stream section to a long distance of unsampled stream. In addition, judgment has been used to estimate the upper extent of fish access in many of the streams. This could lead to considerable error. Many of the streams were accessed by boat and walking up from the mouth of the streams. Sample sites on these systems tended to be located on the lower ends of the streams, and may not truly reflect more typical habitat in the mid-reaches of the streams.

Many of the streams that had coho juveniles present were minor contributors to the production estimate in Table 4. For

example, the estimated combined production from 18 streams where juvenile coho were present represented just over 2% of the total coho fry numbers estimated in the 36 streams.

The results of the sampling suggests that none of the inlet tributaries to Babine Lake provided major rearing habitat to Babine coho populations during the late summer. The combined fry and yearling estimates did not exceed 6700 juveniles in any of these systems. The numbers of juveniles that are present in these tributaries could have been derived from a few pairs of spawners in each creek. The presence of yearlings only in some of these systems (Table 4) suggests that coho use can be sporadic and only occur during some years. Several Morrison Arm streams identified by Hatlevik (1981) as coho rearing streams did not have coho present during these surveys (eg. Tributary 4790 and 4820 in Figure 6).

The presence of coho juveniles in the lower ends of some very small streams such as Tributary 6325 in Red Bluff Park (0.5 m wide) suggests that fry may move up into this creek from the lake. This stream was considered very small for adult coho to use for spawning. Several other creeks possessing juvenile coho were so small that they didn't appear on the 1:50,000 topographic maps. Flows in many of these creeks examined during the late summer were just a trickle.

The most productive coho streams tended to be clustered at the north end of Babine Lake (Figure 4 and 5), Morrison Arm (Figure 6) and south of Topley Landing (Figure 7). It is interesting to note that these areas are close to systems with good coho escapements (Upper Babine River and Fulton River) or historic spawning populations (Morrison Creek).

At the same time, no juvenile coho were captured in the Fulton River, and use of Pinkut Creek was minor relative to the size of the spawning population in this system. Studies by Dr. Mason (DFO, personal communication) indicate that coho fry leave the Fulton River during early July and none are present by late July. This appears to be a response to high water temperatures in this large lake-headed system. Water temperatures taken during sampling in August in Morrison and Pinkut creeks and the Fulton River were in the 15-16 C range and were substantially higher than temperatures in the smaller coho streams indentified in Table 4. Temperatures in these smaller streams ranged from 8-12 C during the August sample period (Appendix 2). The lower Sutherland River was 12 C during late August.

The results of the sampling suggest that the bulk of the juvenile coho that are spawned in the inlet tributaries to Babine Lake move into Babine Lake by late summer and rear in the lake until smolt migration the following spring. It is probable that in some instances juvenile coho move up into the lower ends of tributary streams. As well, a small number of coho appear to spawn in the inlet tributaries identified in Table 4. The total numbers of juveniles estimated to rear in these tributaries during the late summer are low relative to the amount of habitat available in these smaller streams.

No estimates of coho smolt numbers leaving Babine Lake are available so the estimated contribution from inlet tributaries compared to lake-rearing juveniles cannot be made. However, the contribution to the overall coho rearing in the Babine system from these smaller tributaries has to be relatively small, compared to what must be occurring in Babine Lake itself and in the system downstream of the upper Babine River (Nilkitkwa Lake) based on the numbers of spawners that are reported at the fence (Table 1).

A review of literature describing the catch of juvenile coho in Babine Lake during extensive purse seining studies in the lake (eg. Scarsbrook and McDonald 1970 and 1973), indicate that coho juveniles were rare in these mid-water sample areas. It is assumed that coho juveniles are rearing in the shallow marginal areas along the lake shoreline, particularly in some of the extensive vegetated areas such as in Morrison Arm, the Smithers Landing area, Nilkitkwa Lake, and near the mouth of the Sutherland River.

3.3 Potential Fry Outplanting Sites

Three areas that might be suitable for coho fry outplantings were identified during the studies. The sites were barren of fish and the habitat and stream temperature regimes appear to be suitable for supporting populations of rearing coho. The three sites are:

- 1.) Upper Nine Mile Creek (Trib. 3000) in the vicinity of the main road crossing.
- 2.) Upper Tributary 3200 (south fork) in the vicinity of the main road crossing.
- 3.) Upper Twain Creek - this system is barren at the main road crossing, but may be more suited to trout production.

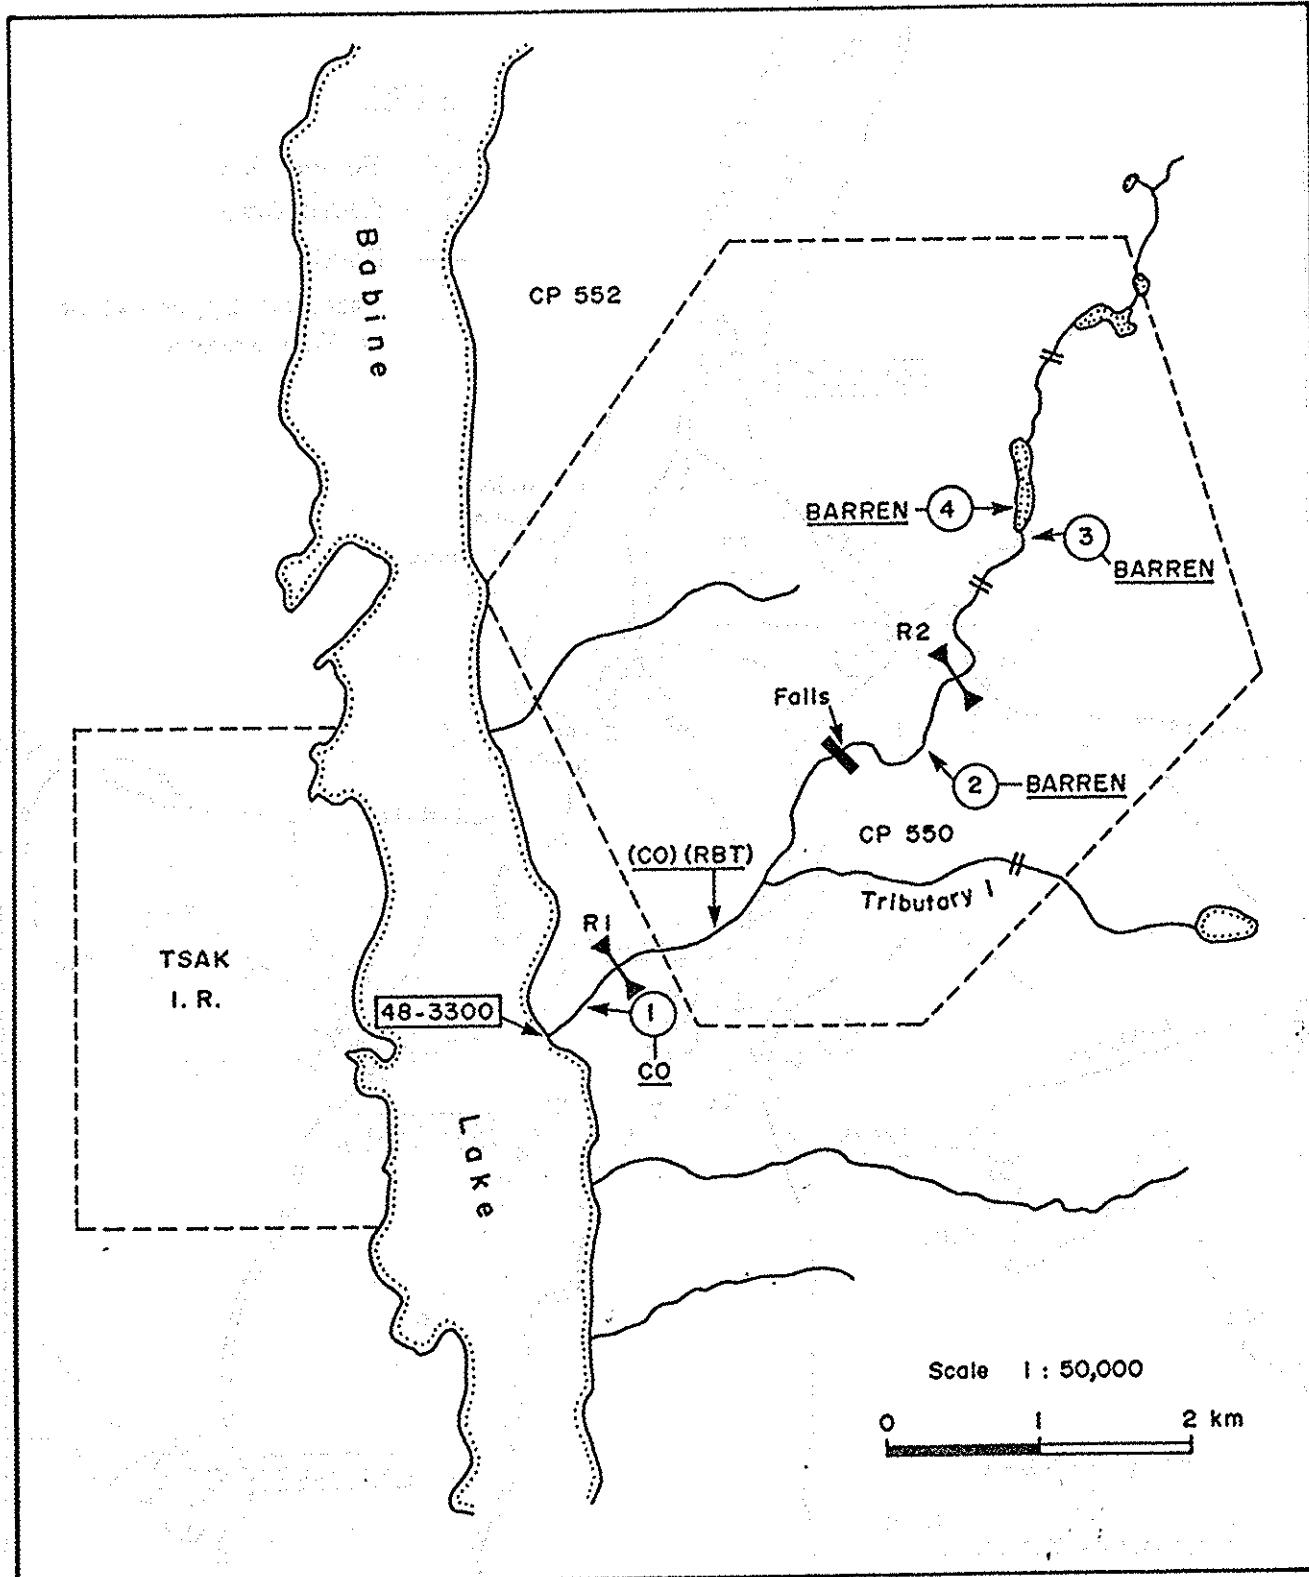

Figure 5. Tributary 3300 near north end of Babine Lake.

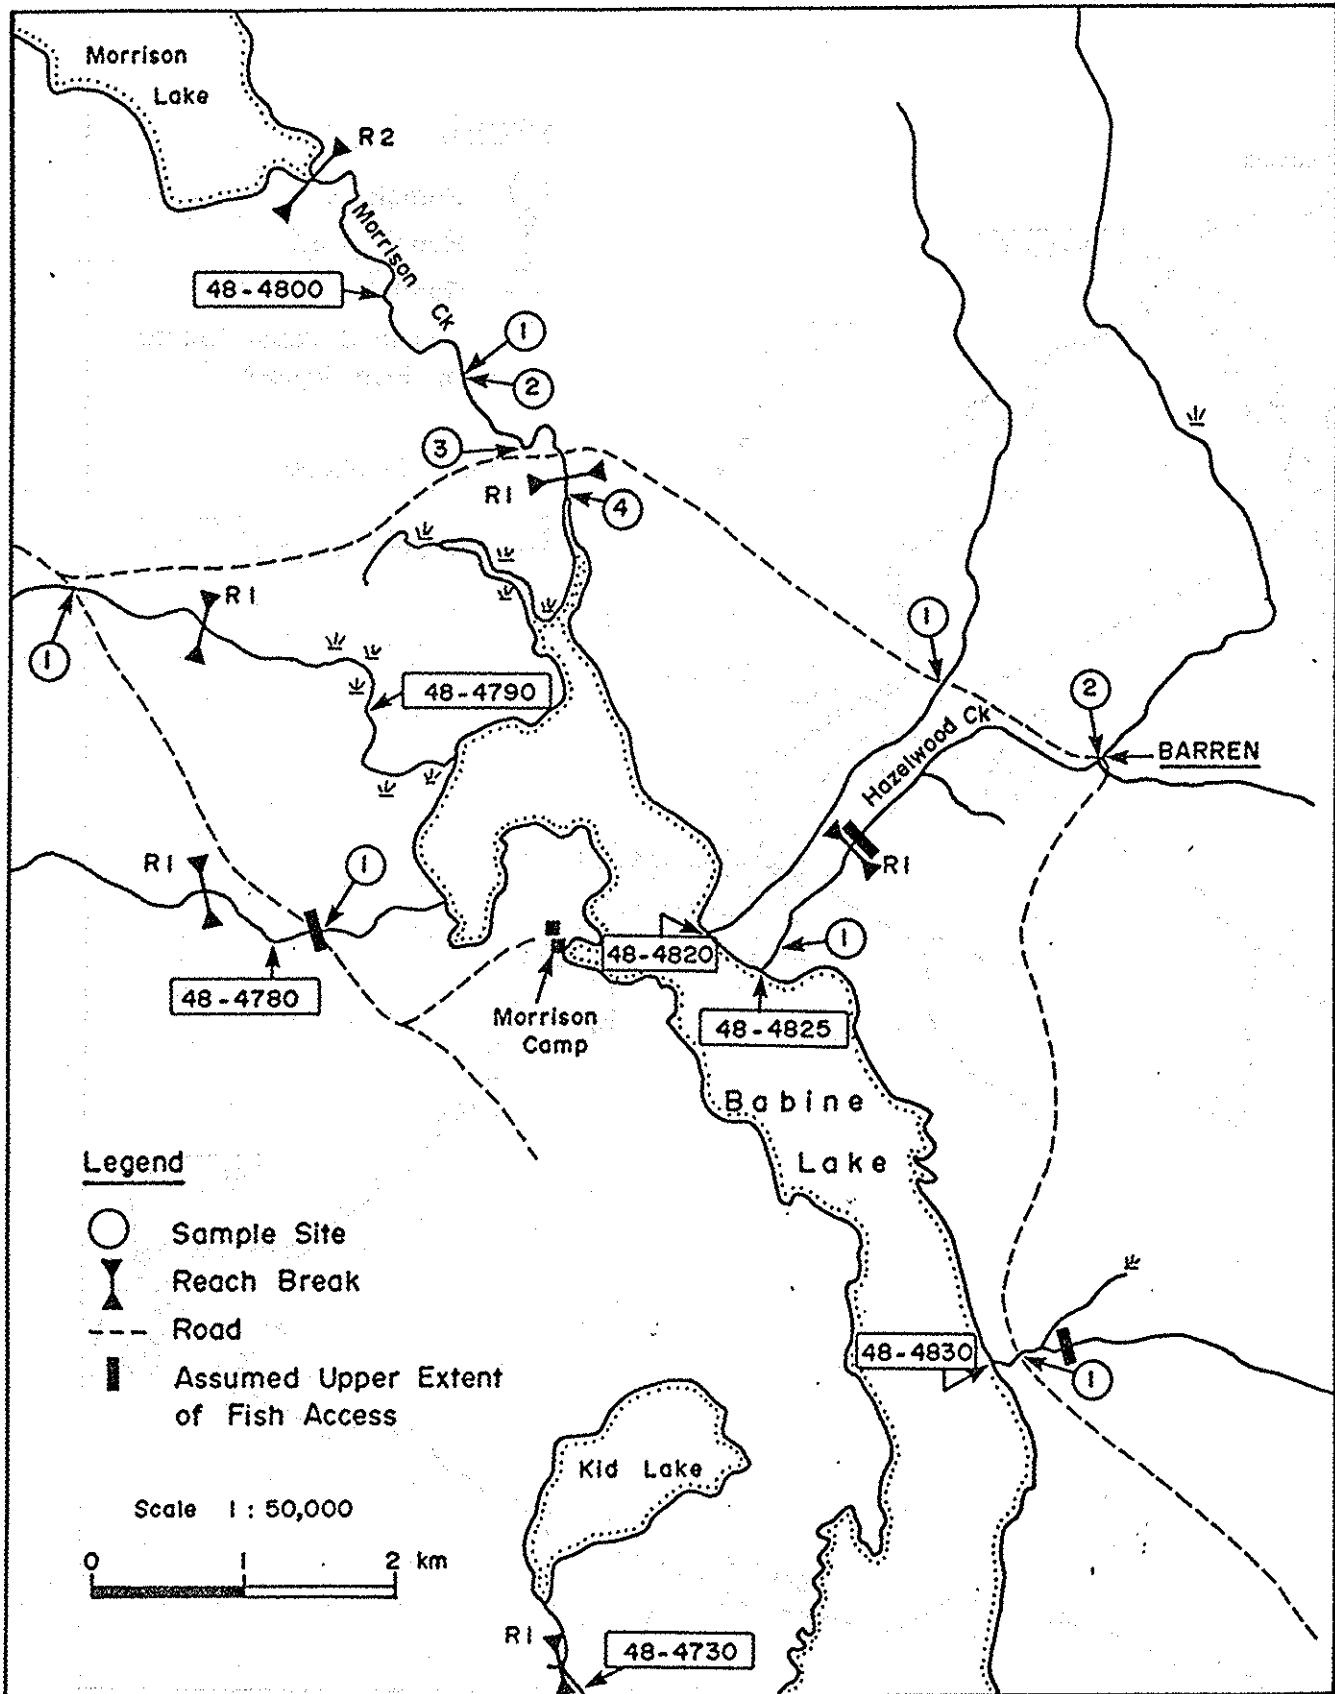

Figure 6. Coho tributaries in Morrison Arm area of Babine Lake.

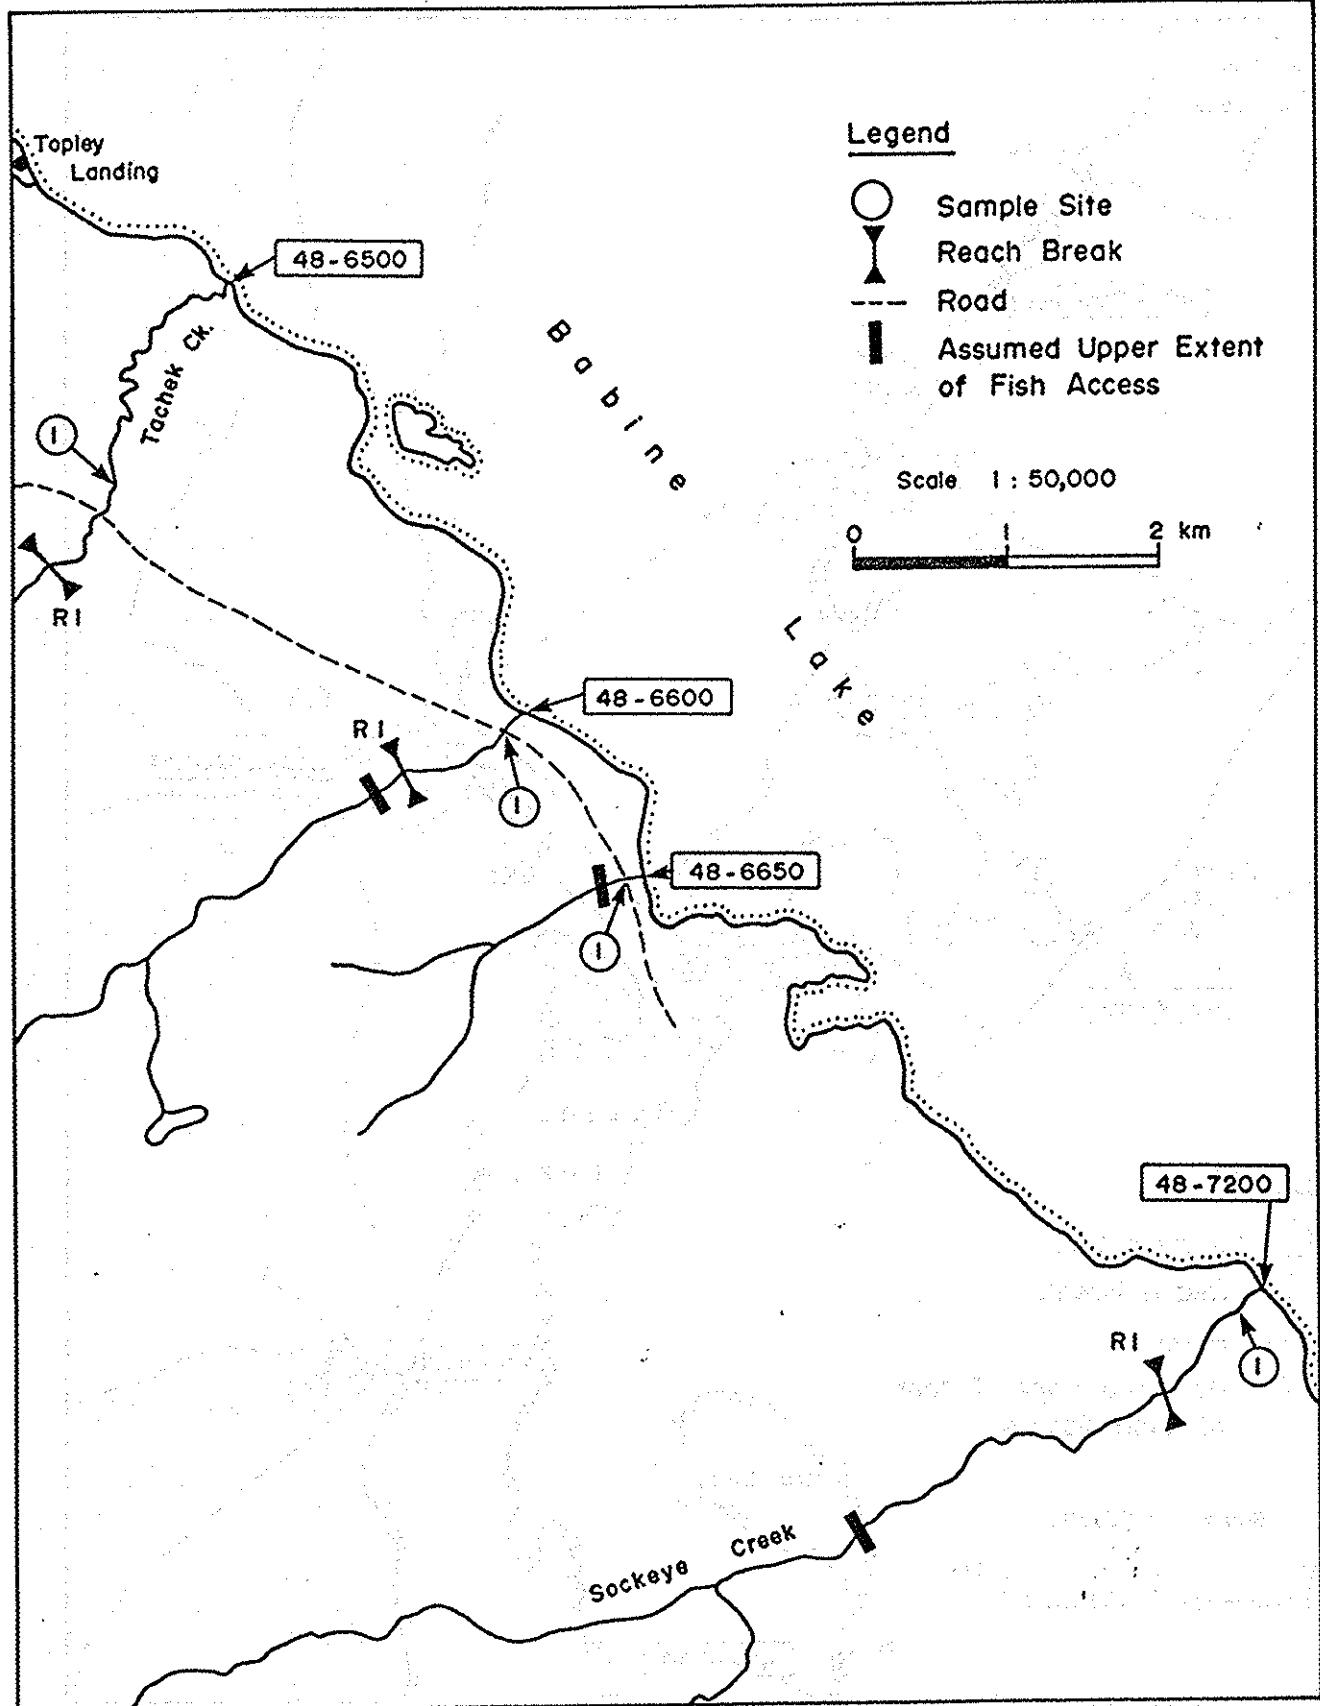

Figure 7. Coho tributaries in vicinity of Topley Landing.

4.0 MANAGEMENT RECOMMENDATIONS

- 1) Coho production in inlet tributaries to Babine Lake is scattered amongst a large number of relatively small tributary streams. Based on the low fry numbers, many of these creeks must rely on a few pair of adults to colonize the streams or upon the movement of fry up into the lower ends of the creeks from the lake. The streams tend to possess abundant habitat relative to the number of juveniles present in the streams. It is important to determine the strategy of juvenile fish in these streams, and whether higher densities are present in the tributaries earlier in the year than when the sampling was conducted. Road development and logging in these small creeks could impact fish using them. Several of the coho streams sampled during this study had been logged across including Tributary 4675, the seventh most important coho rearing stream sampled.
- 2) The key coho rearing areas in the system are probably located downstream of the main spawning area located in the upper Babine River. The role of Nilkitkwa Lake and its inlet tributaries to coho rearing is important to determine.
- 3) Coho smolt movements at the downstream trap should be monitored to estimate the numbers of smolts leaving Babine Lake. The overall role of lake rearing versus inlet tributary rearing could be assessed based on deriving an estimate of smolts leaving the lake outlet.
- 4) Efforts should be made to derive estimates of coho spawning in the Sutherland River and the rearing strategy of juvenile coho using this system. This one system alone possesses more potential coho rearing habitat than most of the other inlet tributaries to Babine Lake combined.

COMMENTS: Sockeye spawning heavy in section.
Fry habitat good along edge. But short length of suitable channel.
Bob Lamond indicates 200-300 juveniles (yearlings)
trapped in channels when they are dewatered in July.
Suspects Rbt spawning at mouth.

SITE MEASUREMENTS:

LOCATION (m)	WIDTH (m)	MEAN DEPTH(cm)	MAXIMUM DEPTH(cm)	BANK COVER	DEER IS COVER	D50/D90 (cm)
0	2.3	8	15	Limited cover at these flows.	3/5	
5	2.4					
10	3.0					
15	1.9			Pool %	Riffle %	
20				COMMENTS: Streamflow quite low 1-2 cfs - lots of subsurface flow in section		
25				Much of the spawning area is high and dry.		
30				Poor parr habitat due to low flows and lack of deep pools.		
				Gravel extends for 0.5 miles downstream of Shass in Suth.
