- APPENDIX L. SALESLIP CATCH AND FIELD EFFORT DATA FOR AREA 3 SEINE AND AREA 4 GILLNET COMMERCIAL FISHERIES.

### INTRODUCTION

Skeena River (Figure 1) chinook salmon (<u>Onchorhynchus tshawytscha</u>) are the second largest wild chinook stock aggregate in British Columbia, second only to the Fraser River. Skeena chinook are renowned for their large size with a number of records of fish over 100 pounds (Figure 2). The Skeena chinook stock aggregate includes over 75 discrete spawning populations. The three spawning populations exceeding 5,000 spawners (Kitsumkalum, Morice, and Bear Rivers) represent 73.3% of the total Skeena chinook spawning population in the 1980's. Skeena chinook escapements declined from the 1950's average of 49,000 to an average of 24,000 over the next 2 decades, then escapement levels increased to average 57,000 since 1985. Until the 1880's the First Nation fisheries in the Skeena area were the major chinook harvesters. Currently, Skeena chinook run a gauntlet of directed and incidental harvests from as far away as the Alaskan trawl fisheries in the western Gulf of Alaska. The total exploitation rate (excluding unknown native harvests) averages 48% (45% ocean) for Kitsumkalum and 16% (11% ocean) for upper Bulkley chinook.

Skeena management has changed significantly over the last decade, particularly since 1993 with the formation of the Skeena Watershed Committee. Interest, concern and the need for chinook assessments on the Skeena are high. PSARC reviewed Skeena chinook in 1989 (Riddell and Snyder 1989) but there has been considerable new information collected in the interim and a new assessment is warranted. This report contains lengthy Appendices of background information as the intent is to provide detail as an information source for the Skeena Watershed Committee deliberations in addition to providing a summary of the available stock assessment information for the Pacific Stock Assessment Review Committee (PSARC).

### CHINOOK STOCK CHARACTERISTICS

# **Escapement**

# **Escapement Data Sources**

DFO inspectors first produced escapement records for Babine sockeye in 1904 (Smith and Lucop 1966). Escapements for species other than sockeye were first recorded in the 1920's. The early inspection reports provide only subjective assessments of relative abundance, generally using phrases like "light", "heavy" or "better than 1923". The first large scale investigations of Skeena River salmon by the Fisheries Research Board, 1944 to1948 produced the first series of escapement data and established the Babine Counting Fence (Pritchard, 1948). With the major DFO reorganisation in 1947, Fishery Officers began to use letter designations for escapements estimated to fall in a given

range. Jantz et al (1989) contains a summary of the evolution of DFO escapement record keeping by Hugh McNairnay (Appendix A).

Escapement data for Skeena watershed streams presented in this report originate from electronic files (Excel spreadsheet format) available (to DFO) on the North Coast network N drive. Data files contain streams geographically organised by subareas (Figure 3). Chinook escapement data, by stream since 1950 is provided in Appendix B. Information for each stream is recorded by year and grouped by decade. These files generally agree with the DFO salmon escapement database (SEDS) maintained by the Pacific Biological Station in Nanaimo (Serbic 1991), however there are some differences yet to be resolved (Table 1). A program to review all original Skeena escapement records and update the SEDS files is underway and will be completed by July, 1996. The North Coast Statistical Area escapement information is maintained and co-ordinated by Brian Spilsted, North Coast Stock Assessment Unit Prince Rupert (Tel: 604-627-3462).

The Skeena watershed chinook escapement data are mainly derived from Fishery Officer visual estimates conducted by foot, boat or aerial surveys. These escapement records have been reported since the early 1950's. The level of accuracy is unknown but presumed to be low because of the variability in visibility, frequency of surveys, changing methods of observation, variable fish abundance, and differences among pilots and among observers.

Riddell and Snyder (1989) compared escapements for streams with observations in 9 of 10 years against the reported escapements for all streams. The consistently surveyed streams represented 90.4 % of the total escapement on average with no clear temporal trends. North Coast salmon escapements were reviewed in 1993 to evaluate trends in stream enumeration patterns and coverage (Spilsted pers. comm.). The designations 0, not inspected, non-observed and unknown were used arbitrarily with no consistent patterns among areas or years. Interpretation of these reporting categories varied widely among Fishery Officers in 1994, with the majority not used as defined. The Department of Fisheries and Oceans (DFO) reorganisation in 1993 resulted in Fishery Officer duty reassignments, particularly in the interior areas of the Skeena watershed. This resulted in reduced surveys in 1993 and 1994, the most significant impacts being the loss of surveys of the Bear and Morice systems two of the largest Skeena chinook populations. The 1995 Skeena escapement surveys were covered by a contractual arrangement with John Hipp a former Terrace fishery Officer very experienced in escapement enumeration. Escapement priorities for the Skeena were set by a joint Stock Assessment, Operations and Habitat Enhancement Branch committee. The important (based on size, value as an index of escapement or harvest) chinook stocks were made a priorty for escapement enumerations (Table 2), however resources allowed only two and for some systems one annual observation. We reviewed in detail the original escapement documentation for Stephens Creek, a very small inconsistently surveyed stream (1980's average 180 spawners),

Kloiva Creek a small accessible regularly surveyed stream (1980's average 228 spawners), Kitwanga River (1980's average 677 spawners), and a large Skeena tributary the Bear River (1980's average 10,480 spawners). The intent was to demonstrate the nature of the information on inspection methods, number of visits and reliability of the estimates. Stephens Creek has been surveyed irregularly with the method of survey changing from unspecified to helicopter beginning in 1986 (start of PST funding). The number and dates of the surveys have been recorded for most years (Table 3). The Kloiya has been walked in almost all years, the number of visits and the date of the inspections have been recorded since 1984 (Table 4). The Kitwanga has been surveyed by helicopter since 1986, and the dates of inspection and the number of visits are recorded from 1948 to 1991 (Table 5). The Bear has been inspected by helicopter in the most recent period (1984 to 1995), while a plane was used 1970 to 1980 with methodologies unknown prior to 1970 (Table 6). The dates of the surveys have been recorded for most years since 1950. There was a shift in methodologies for all areas beginning in the 1984 to 86 period but since the change coincided with the PST management alterations (and the subsequent increase in chinook spawners) we cannot determine to what extent, if any, the escapement estimates changed because of the increased use of helicopters. The enumeration of the Kloiya was less frequent in recent years compared to 1957 to 1983 when there was a guardian on site, and observers have changed from Fishery Officers to Hatchery crew.

# **Fishery Officer Observations**

Since 1953, chinook have been observed spawning in 75 streams throughout the Skeena watershed. The distribution of spawner abundance is highly skewed to the lower spawning population sizes:

| Range of Spawning<br>Escapement<br>(average 1980-89) |       | Number in Category |
|--|-------|--------------------|
| No r   | ecord | 23                 |
| 1 to   | 50    | 21                 |
| 50 to  | 499   | 20                 |
| 500 to   | 999   | 5                  |
| 1,000 to   | 4,999 | 3                  |
| >  | 5.000 | 3                  |

The three spawning populations exceeding 5,000 spawners (Kitsumkalum, Morice, and Bear Rivers) represented 73.3% of the total Skeena chinook spawners in the 1980's. Adding the next category (Ecstall, Kispiox and Babine Rivers) adds 13.4%, so the top 6

streams contributed 86.7% of the observed chinook spawning escapement in the 1980's.

Appendix B contains the annual Skeena escapement data by tributary since 1950, with a summary of trends by subarea. Figure 4 includes the Fishery Officer Skeena chinook escapements since 1950. Skeena chinook escapements declined from the 1950's average of 49,000 to an average of 24,000 over the next 2 decades, then increased abruptly during the period 1985 to 1993 with escapements varying between 52,000 to 68,000 (average 57,000). There was a strong decline in escapements in 1994 and 1995 that is also reflected in the escapement trends by subarea (Figure 5). Although there is some variability among systems there is no apparent trend related to geographical area. The annual escapements for each Skeena Watershed stream regularly surveyed (12 of 15 years) during the period 1981 to 1995 are plotted in Figure 6. Although there are variable patterns in escapement there is no evident trend related to the size of stock. The enumeration effort in some streams changed with the Fishery Officer reorganisation, beginning in 1994, and this complicates the interpretation of the escapement decline in 1994 and 1995. We did not attempt to reconstruct the stream specific escapement methodologies to clarify whether some of the stream specific changes were due to reduced enumeration effort.

### **Babine River Weir Count**

The Babine weir is located on the Babine River below the outlet of Babine Lake (Figure 7). The weir was constructed in 1946, rebuilt in 1967 and replaced again in 1994. Daily chinook weir counts were obtained from Aro (1961) for the years 1946 to 1961, from Jordan (1967) for the years 1961 to 1966, and from the electronic files maintained by Les Jantz (DFO Prince Rupert) for the remaining years. One interesting feature of the fence data for the period 1962 to 1966 is the round number totals for both the jack and adult counts:

1962 630 adults, 2,400 jacks 1963 1,500 adults, 1,900 jacks 1965 1,200 adults, 2,000 jacks 1966 1,600 adults, 2,500 jacks.

Jordan (1967) makes no mention of anything unusual with respect to data collected for these years, and the daily weir counts are variable and do not look reconstructed. The Babine weir was not operated in 1948 or 1964. The Babine Fence counts for chinook are truncated in some years when the fence was closed early, mainly during the years 1960 through 1974. To provide annual estimates that were comparable for the years when the late counts were missing, the jack and adult data for 1960 through 1974 were

adjusted by adding the average run proportion (by date) for other years which generally represent the complete run. The annual chinook counts did not separate jacks until 1962 as indicated in the data presented in Figure 4. The Babine chinook adult escapement declined during the 1950's and 1960's and was variable with no clear trend until escapement increased from 1989 to 1993. Escapement subsequently declined to very low levels in 1994 and 1995.

Chinook biological sampling data from recent years (1988 to 1995) is reported by Jakubowski 1990a, 1990b, and 1996 (in preparation). This biological sampling information for all years will be entered in the North Coast biological sampling database by the end of 1996.

# Kitsumkalum Chinook Key Stream Escapement Enumeration

A mark-recovery program (tagging live returning adults and recovering tags from carcasses following spawning) to estimate chinook escapement to the Kitsumkalum River has been conducted since 1984. The 1984-86 results are presented in Andrew and Webb (1988), 1987-88 in Carolsfeld et al. (1990), 1989-90 in Nass and Bocking (1992), 1991 in Nelson (1993a), 1992 in Nelson (1993b), 1993 in Nelson (1994) and the 1994 results in Nelson (1995). The reported escapements were:

| Year | Kitsumkalum<br>Escapement | Year | Kitsumkalum<br>Escapement |
|------|---------------------------|------|---------------------------|
| 1984 | 11,825                    | 1990 | 21,039                    |
| 1985 | 8,308                     | 1991 | 9,288                     |
| 1986 | 10,151                    | 1992 | 12,437                    |
| 1987 | 24,508                    | 1993 | 14,059                    |
| 1988 | 22,755                    | 1994 | 12,629                    |
| 1989 | 18,287                    | 1995 | 7,221                     |

This data is also represented graphically in Figure 4. Unfortunately, the Fishery Officer counts were not continued in parallel to this program so there is no direct insight into how the Fishery Officer estimates compared to the mark recovery calculations. However, the escapements derived from the mark-recovery program were similar to the previous Fishery Officer estimates for 1984 to 1986, which supports the notion that the two estimates were in the same range, The estimates increased significantly beginning in 1987, but this was consistent with increases in most of the Skeena chinook stocks in this period, and does not necessarily suggest the estimates increased because the enumeration technique changed (Figure 5),

# **Other Escapement Enumeration**

Neilson and Geen (1981) evaluated chinook spawning escapements to a portion of the Morice River in 1979. The estimated the Chinook spawning population to be 2,826 and noted the maximum single count from the 7 helicopter surveys was 52% of their estimated total escapement in the study area. Since this survey represented only a portion of the escapement to the Morice, and the DFO counts in the equivalent portion are not identified, direct comparison is not appropriate. This study indicates that single surveys significantly underestimate the total spawning population. The underestimate would be even greater if the survey missed the peak abundance.

A fence was operated on the Bear River (by Environmental Quality Unit, DFO to provide background data for an evaluation of the potential impacts of dam development) from August 9 to October 19, 1972 and 3,452 chinook salmon were counted (Kussat 1973). The DFO escapement record indicates 3,100 chinook spawners and the original escapement record forms make no mention of the counting fence. If these are independent assessments the results are encouragingly similar.

A fish counting weir on the lower Sustut River in 1994 counted 956 chinook but missed the early portion of the run (Saimoto 1994). The chinook weir count in 1995 was 1,021 (pers. comm. Barb Snyder). The DFO estimates correspond quite closely (1994 was 1,055 and 1995 was 972) but they are not believed to be independent estimates.

A radio tagging program was implemented in 1985 to study early run chinook salmon stocks returning to the upper Kitsumkalum River watershed (Alexander and English 1996). These Cedar River and Clear Creek chinook stocks are of concern because escapements are low (Appendix B). The purpose of the study was to confirm the locations of major spawning areas, collect information on in-river migration timing of chinook and to estimate the escapement of early run chinook salmon to the Kitsumkalum River. The program confirmed the timing separation between the early and late run Kitsumkalum chinook, established the early run spawning areas (Cedar River 82%, and Clear Creek, 18%) and provided a spawning population estimate of 658 chinook (Figure 8). The DFO independent escapement estimate of 580 (from helicopter overflights) differs little from the mark-recovery estimate.

# Timing of Skeena Chinook Spawning

Skeena chinook spawning timing is summarised in Appendix C (Description of methods and two figures from Jantz et al. 1989). The data is organised geographically from the Skeena River mouth to upstream areas. Chinook spawning generally occurs in August and September. Spawning in the lower Skeena coastal area occurs predominantly in

September. The spawning peak for chinook stocks in the Skeena downstream from Terrace is earlier, mainly in August. The two Terrace sub-areas, Kitsumkalum and Lakelse, both have an early (August) and a late (September) component to the escapement. The Skeena tributaries above Terrace are variable in their peak spawning times throughout August and September, with the Upper Bulkley being a notably early spawning population.

The observations of Shepherd (1979) that chinook migrations into the Morice system begin the end of July, with peak spawning in mid-September and die off by mid-October agree with the summary data in Appendix C.

Healey (1991) analysed the relationship between medial spawning date and latitude. Using the regression from Healey (p. 320), the Skeena median spawning date was predicted to be July 22. The Skeena escapement data indicated an approximate median date of September 1, which is still within the normal range of variability of the relationship.

### **Skeena Test Fishery**

The Skeena Management Committee created the Skeena test fishery in 1955 to provide an index of salmon escapement past the commercial fishing areas. Skeena gillnet test fishery is located at Tyee in the tidal waters at the mouth of the Skeena (Figure 3). The test net consists of 10 panels ranging in size from 3.5" to 8" mesh in 1/2" increments, making the net effective over a broad range of salmon sizes. The net is fished during daylight slack tides for 1 hour per tide, and a daily index is calculated based on the daily average catch per hour. A detailed description of the site and methods is available in Kadowaki (1977). An important change in the methodology (size-catchability relationship) was introduced by Kadowaki (1985) and recent performance is reviewed in Cox-Rogers and Jantz (1993). The sockeye index is calibrated each year by comparing the total sockeye escapement (a high proportion of which is from the Babine Fence counts) with the in-season test fishery index. There has been a significant progressive decrease in the catchability of the test fishery for sockeye (Cox-Rogers and Jantz 1993). Whether there has been a parallel shift in chinook catchability is unknown since there is no accurate measure of chinook escapement to calibrate the test fishery results.

The Skeena test fishery adult chinook and jack indices, standardised to the annual period June 15 to August 15, are presented in Figure 4. A striking feature of the jack indices is the precipitous decline in 1991 and the continued low jack catch from 1992 to 1995. We reaffirmed that the test fishery staff normally sampled all (or an unsorted subsample during high catch periods) of the chinooks caught at the test fishery.

# **Chinook Ageing**

### **Vancouver Ageing Laboratory**

Fish aged at this facility are recorded using the Gilbert-Rich scale age designation system (Gilbert and Rich 1927). Precise scale age determination can be affected by the degree of scale resorption. If a resorbed scale is encountered, an attempt is made to interpret the true age of the fish (J. Till pers. comm.). When available, Coded Wire Tag (CWT) and fin ray data can be used to confirm interpreted ages.

An electronic age database was established in 1989 and contains age and sampling information. Age information prior to 1989 has not been entered into the database.

### Pacific Biological Station Ageing Laboratory

Salmon ages are documented using the European scale age designation system (Koo 1962). When resorbed scales are encountered, a resolved may not be determined unless CWT or Fin Ray data is available. No annuli are added to a resorbed scale to compensate for loss due to resorption. The scale age given is the best estimate of only the number of annuli visible on the scale and as a result some under-ageing may occur (D. Gillespie, pers. comm.). Information generated by the lab is retained on ageing sheets, but not entered into an electronic database. Ageing formation prior to 1980 is saved as archive material and stored at the Pacific Biological Station (PBS).

### **Review of Skeena Historical Age Data Records**

All the original Vancouver scale lab chinook scale books for samples taken within the Skeena watershed were reviewed and the data compiled for this report.

A database was set up summarising chinook scale age information from the Vancouver and the PBS Ageing Units. A description of the database fields is included as part of Appendix D. PBS data contain 32 smolts aged in 1994 (Sustut), while the remaining data represent adult ages. Vancouver data represent adult ages only. The data does not include information on the sex of the chinook. Summaries of the number of chinook aged by the Vancouver and the PBS scale labs from samples taken from the Skeena watershed for the years 1973 to 1995 are provided in Table 7. Data for the Skeena Test Fishery, Kitsumkalum River, Kispiox River and Babine River show the longest time series with 23, 20, 16 and 20 years respectively. Samples are represented from 26 Skeena tributaries, although only 10 have more than 100 scales in total for all years. The Kitsumkalum River has relatively high sample sizes with annual coverage. The Babine

Fence recoveries usually provide annual sample sizes exceeding 100 chinook. The Bear, Bulkley, Cedar, Copper, Ecstall, Kispiox, Morice, and Sustut have intermittent sampling with highly variable sample sizes.

# **Skeena Chinook Escapement Age Structure**

The detailed annual age structure for each project listing is available in Appendix D. As is indicated in the previous section, many of the sample sizes are very low. Data on the annual age proportions by year (with averages for the 1980 to 1995 period) from the Skeena Test Fishery, Kitsumkalum River and Babine River are outlined in Table 8. In the Skeena test fishery samples, age 5 sub 2 and 6 sub 2 are the most abundant (42% and 33% respectively), with age 4 sub 2 representing 16%. The remaining 9% is spread among a variety of other ages. The Kalum age structure is skewed more towards the older ages with 6 sub 2 being the most common (64%) followed by age 5 sub 2 (25%) with ages 5 sub 1, 5 sub 2 and 4 sub 2 all represented at about 3%. The pattern in the Babine is reversed with age 5 sub 2 (56%) the predominant age and age 4 sub 2 (19%), 6 sub 2 (16%) and 3 sub 2 (9%) also represented. This pattern seems to be generally present in the other tributaries with the Terrace area stocks (Cedar, Copper and Kispiox) showing a similar pattern to the Kalum and the other upper river samples (Bulkley, Morice and Bear) tending to be similar to the Babine age structure (Appendix D).

# Skeena Chinook Sex Specific Age Structure

There are distinctly different maturity schedules for male and female Skeena chinook based on analysis of the 1990 to 1995 Skeena test fishery samples (Table 9). The females were predominantly age 5 and 6 (40.9% and 54.6% respectively), with very few age 4 (2.9%) and age 7 (1.6%). The male age structure was mainly age 4 (32.4%), age 5 (36.4%, and age 6 (25.9%), with a small percentage of age 2 (.1%) and age 3 (5%).

# Ocean versus Stream Type Chinook Scales

Gilbert (1913) designated two chinook life history forms based on stream residency. A "stream type" spends at least one winter in freshwater and an "ocean type" migrates to sea in it's first summer, does not have a freshwater annulus and would have a subscript 1 (or written sub 1). Reports from the 1960's and 1970's indicated a very high proportion of sub 1 chinook in Skeena samples (Godfrey 1968, 57.8 % sub 1; Healey 1983, 52%). The ageing methods were revised in 1978 for Fraser chinook (Tutty and Yole 1978) and for all chinook scale readings beginning in 1980. Table 10 shows total sub 1, 2, 3 and 4 chinook for each Skeena escapement sub area for the years 1980 to 1995 for the Vancouver scale lab and for 1984 to 1995 for the PBS scale lab. Scales from years prior to 1980 were excluded as some scale readings for this period have not been reread (1977 and 1978 Skeena test fishery for example). Data from our review indicate stream type chinook are

dominant as sub 1 chinook represent only 4.1 % of the Vancouver scale lab data and 1.1 % of the Pacific Biological Station (PBS) data. There is a trend of decreasing proportions of sub 1 ages from the mouth (Coastal sub area) through to the upper Skeena (Sustut sub area). The coastal sub area ages were 16.7 % sub 1 from the Vancouver lab data. In the few areas of overlap between the Vancouver and PBS databases they are in close agreement:

Kitsumkalum Vancouver 4.9% sub 1 PBS 3.6% sub 1
Bulkley/Morice Vancouver 1.7% sub 1 PBS .6% sub 1
Sustut Vancouver 0% sub 1 PBS 1.0% sub 1.

# **Chinook Length at Age**

Postorbital-hypural length and age data for chinook sampled from the Skeena test fishery for the years 1990 to 1995 were summarised from the North Coast stock assessment biological database. Biological sampling information recorded in the database follow a standardised format as recommended by Shaw (1994). The data entry is incomplete but will continue through the final year of Skeena Green Plan funding, to encompass the majority of Skeena programs where biological samples are collected.

A summary of the available length at age information for the Babine Fence, Skeena test fishery and Kitsumkalum River and single entries for the Skeena terminal gillnet fishery, Cedar River and Upper Bulkley River are presented in Table 11. General trends in the data showed Babine, Upper Bulkley and Cedar stocks smaller at age than the test fishery and Kitsumkalum chinook larger at age than the test fishery. As would be expected age 4 sub 2 chinook were smaller than age 5 sub 2 which were smaller than age 6 sub 2. There appeared to be no consistent differences in length at age between sexes, although a rigid statistical comparison was not attempted. The reports on the Kitsumkalum stocks (Table, 11) make annual statistical comparisons of differences between sexes and sections of the river but there are no consistent patterns. The Skeena test fishery length frequencies are plotted for the years 1990 to1995 by sex by age (Appendix E). The data shows a number of very small size chinook that are well outside the common lengths which may indicate fish that were incorrectly aged.

Data from Kispiox and Upper Bulkley SEP programs exist as raw data but were not obtained for this report. Other data not included in summary Table 11 because the ages are believed to be incorrect are available in other reports. Godfrey (1968), reported age and physical characteristics of chinook salmon from the Skeena River in 1964, 1965, and 1966. Harding and Buxton (1971) reported length frequency of dipnetted chinook from Moricetown for 1961, 1962, and 1965 and for chinook captured by gaff or gillnet in 1964. They also calculated nose-fork to post-orbital hypural length conversion factors for salmon

captured in the Moricetown gaff and gillnet fishery 1964. Shepherd (1979) reports chinook length frequency distributions by sex and age for Morice River chinook spawners in 1974.

# **Fecundity**

Godfrey (1968) summarised fecundities for Skeena test fishery samples by year by flesh colour for the years 1964 to 1966. The Cedar River chinook fecundity from the 1989 egg take averaged 6,079, (n=9 std=1,693), calculated from Terrace Salmonid Enhancement Society (1989) data. The 1988 fecundity data from the egg take averaged 7,253 (n=18 std=1,329), again calculated from the Terrace Salmonid Enhancement Society (1988) data. A mean fecundity of 7,300 was reported for the pilot Kitsumkalum River Hatchery production 1980-82 (Morgan 1985). This fecundity information is of little biological interest without associated length and age information to derive fecundity-length relationships.

# **Egg Retention**

Morgan (1985) reported average egg retention of 2% for 175 female chinook carcasses examined during 1978. The egg retention for chinook sampled from the Babine Fence (1991-1994) is summarised in Table 12. There is evidence of some pre-spawning mortality in these Babine samples with annual variation ranging from high mortalities in 1993 when 33% of the sockeye sampled (n=9) retained half or more of their eggs to a low incidence in 1994 when none of the sockeye sampled (n=117) retained more than half their eggs. In recent years pre-spawning chinook mortalities have been noted by fence staff and are generally associated with unusually high water temperatures (Mike Jakubowski pers. comm.).

### Flesh Colour

A total of 87% of the chinook sampled in the Skeena test fishery from 1964 to 1966 had red flesh (Godfrey 1968). Tallman (1995) reported that 71% of chinook caught in the lower Skeena River sport fishery in 1995 had red flesh.

# Chinook Fry Migration

Emigration of emergent chinook fry in the Kitsumkalum River system from 1977 to 1980 indicated peak movements occurred during late April and mid-May (Morgan 1985). Williams et al. (1985) reported Bear River chinook fry emigration peaked between May 30 and June 25. Shepherd (1986) reported that in 1984, newly emerged chinook fry in the Morice River emigrated mainly during the period from mid-April through early June with the peak in late April. A juvenile monitoring program (rotary screw trap) in place on the Sustut system in 1994 indicated that chinook fry moved downstream in large

numbers from May 31 to June 8 with the peak from June 5 to June 7 (D. Bustard and Associates 1994a). Healey (1991) reports that large downstream movement of fry immediately after emergence is typical for most chinook and Skeena chinook seem to behave in this manner.

The 1994 Sustut chinook fry migration was estimated to be 1,291,759 extrapolated from the catch of 73,817 (D. Bustard and Associates 1994a). This represents a minimum estimate as the chinook fry migration had started before the weir was in place and continued past the end of this study. This fry output was from an escapement estimated to be 1200 to 1600 (the previous years chinook weir count was 199, but covered an unknown proportion of the run. Provincial staff did a swim survey of the system and reported 1200-1600 spawning chinook (the DFO escapement record shows 199). If the lower escapement levels were accurate and assuming a fecundity of 7,000 the egg to fry survival would be 92%. If 1400 spawners were present, then the egg to fry survival would be 13.2% which is more plausible. Healey (1991) reported chinook egg to fry survival varies widely, but "under natural conditions, 30% or less of the potential eggs deposited resulted in emergent fry".

# Juvenile Chinook Sizes

Information on Skeena River juvenile chinook length and weight information is summarised in Table 13. Spring fry lengths and weights showed little variation among tributaries. Bustard (1994a) reports 1994 Sustut chinook fry averaged 38.8 mm fork length and .4 g in weight in late May - early June. The weir location was within 5 km of the main chinook spawning areas and so these are assumed to be recently emerged fry. Sustut chinook fry in May of 1995 averaged 38.9 mm fork length (Chris Wood Pers. Comm.). Kitsumkalum River chinook fry in April 1978 averaged 40.4 mm fork length and .62 g in weight (Morgan 1985). Morice River fry averaged 39.3 mm fork length and .52 g weight in April of 1979, and averaged 36.8 mm fork length and .57 g weight in April of 1980. Williams et al. (1985) reported a fry size range of 39.3 to 41.8 for the Bear River in 1984.

There are consistent observations throughout the Skeena watershed that chinook juveniles did not rear in the vicinity of the chinook spawning areas, but migrated out of the smaller tributaries into the main tributaries or perhaps the Skeena River mainstem. Bustard (1994a) reports a 1994 spring migration of 2,672 chinook smolts (averaging 75.5 mm fork length and 4.5 grams weight). This low number of chinook smolts is consistent with the observations of Bustard (1994b) who reported that in Sustut juvenile surveys he conducted in 1992 and 1993 that there was little evidence of chinook juveniles rearing more than 1 km upstream in Johanson Creek or in the Sustut River upstream of the confluence with Johanson Creek. Therefore there is a relatively small section of stream to produce the chinook smolts counted in the 1994 smolt program

program. Bustard (1994b) reported that significant numbers of chinook fry rear along the mainstem of the Sustut River from the Johanson Creek confluence down to the Bear River confluence. Shepherd (1979) failed to locate an abundance of chinook smolts in the Morice River and suggested that juvenile chinook leave the Morice but continue to rear in the Bulkley or Skeena Rivers over winter.

# Chinook Stock Timing in the Terminal Areas

# Aggregate Stock Timing

# **Timing of the Skeena Test Fishery Chinook Escapement**

The timing of escapement past the Skeena River test fishery was summarised by Riddell and Snyder (1989) using Skeena test fishery data standardised to a June 15 start date (Figure 9). The timing for the years 1984-1988 was shifted much earlier than the previous periods. Overall, the data indicates a flat migration timing curve with a relatively consistent abundance of chinook from the standardised start date of June 15 for a 35 or 40 day period (until July 25 to 30). A graph of recent (1990 to 1993) daily average chinook escapement indicates a similar distribution (Figure 10).

In developing the Skeena management model (Cox-Rogers 1994), Skeena test fishery chinook migration timing was summarised by calculating the average cumulative escapement timing by decade (Table 14, Steve Cox-Rogers pers. comm.). The 50% point in the run was July 11 (+/- 2 days) for the 1950's, 1960's and 1970's. The 1980's and 1990 to 1993 data shifted to an earlier date, July 2 (+/- 1 day). The earlier run timing is believed to result from a reduced harvest rate on Skeena chinook in the period prior to July 1 due to Pacific Salmon Treaty (PST) management actions which have disproportionately increased the early component of the Skeena chinook escapement.

# Timing of Skeena Chinook Catch in the Area 4 Gillnet Area

The timing of the cumulative chinook catch in the Skeena River, Statistical Area 4, gillnet fishery was summarised by Riddell and Snyder (1989) (Figure 9). The pre 1973 data indicated an abundant chinook harvest from the second week of June through the last week of July, similar to the pattern in the Skeena test fishery. The fishery during this time period was open throughout the total period of the chinook migration. After 1973 the chinook harvest begins the first week of July when the fishery first opens.

Chinook catches in the most terminal portion of the Statistical Area 4 gillnet fishing area (Figure 11), the river-gap-slough (RGS), represent only Skeena origin chinook (see Skeena Terminal Exclusion page 24). Chinook hail catch estimates prorated to Area 4 sales slip totals, and calculated are presented in Appendix F. Hailed catches are

derived from Fishery Officer interviews of fishers on the grounds. The subsamples are expanded to provide an estimate of the fleet by area. The peak of the chinook catch in the RGS varies from week 7-1 to week 7-4 a peak in week 7-2 or 7-3 most common (Table 15). Catch can be a biased indication of timing. Catch is influenced by abundance and effort. Since effort is not equal in all weeks, the chinook catches are artificially increased in the weeks with higher effort (weeks 7-4 and 7-5).

The CPUE data for most years indicates the peak is likely earlier than the first week of gillnet fishing. This data is also biased, but in the opposite direction, since the effort-CPUE relationship for a given abundance is not linear and the early weeks CPUE with a low effort are inflated relative to the later weeks of high effort (Cox-Rogers 1994).

# **Reconstruction of Area 4 Chinook Catch and Escapement**

As an alternate way of looking at the Skeena chinook terminal timing total Area 4 catch and escapement was reconstructed for the period 1990-1993 (pers. comm. Steve Cox-Rogers, Table 16). The chinook catch peaked week 7-1 (week ending July 2-8).

# Stock Specific Timing

# Cedar River/ Clear Creek Chinook Timing

The 1995 radio tagging study on the early chinook stocks to the Kitsumkalum system indicated the early chinook run which spawned in the Cedar River and Clear Creek entered the lower Kitsumkalum River from late April to late June (Alexander and English 1996).

# **Back Calculation from Morice Fishway and Babine Weir Counts**

Terminal area timing of Babine and Morice chinook stocks can be estimated from the timing of weir and fishway counts by subtracting the migration timing from the terminal tidal area to the fence or fishway.

The Moricetown fishway chinook daily counts are summarised in Table 17 (data from Harding and Buxton 1971). Data from 1959 and 1964 were excluded as partial counts that appeared to miss the main chinook migration period. The peak daily counts occurred on: 1961 July 27, 1962 August 2, 1965 July 29, 1966 July 30 and 1967 July 29. The mean peak date was July 30. The average chinook run timing through the Babine Weir was calculated using the data from 1946 to 1959 and from 1975 to 1995. The years 1960 to 1974 were excluded because the counting operation was stopped

early in those years. The average date that 50% of the chinook run passed through the Babine Weir was September 8.

Skeena sockeye migration rate (summarised from a series of sockeye tagging programs) averaged 13 km per day from the Skeena River terminal fishing area to the Babine Fence (Takagi and Smith 1973). Nass radio tagged chinook salmon averaged 8 to 14 km per day once they were above the Nass canyon (Koski et.al. 1993). Using an assumed 12 km per day migration rate for Skeena chinook, the Babine fence migration timing would translate to peak migration dates past the Skeena test fishery of August 7 based on a distance of 380 km. The Moricetown migration timing would translate to peak migration past the Skeena test fishery on July 6 based on a distance of 283 km. (mileage converted from Table 18, Smith and Lucop 1966). There is uncertainty regarding the effects of the Babine counting fence on the chinook migrations. Chinook hold for extended periods below the fence and it is not clear whether these fish are delayed because of the fence or if they are pausing because the fence is a convenient normal holding area for adjacent spawning areas. Bear River chinook enumerated through a counting weir peaked August 12 (Kussat 1973). Chinook migrating at 12 km per day would take 38 days from the Tyee test fishery. This would suggest this run peaked at the test fishery on July 5.

### **Skeena Chinook Timing based on CWT Recovery Patterns**

CWT recovery patterns are biased indicators of run timing since the sampling rate (fishery harvest rate) varies within and among years. This should be taken into consideration when interpreting the qualitative assessments that follow.

Skeena chinook coded wire tag (CWT) information was obtained from the PBS MRP-Reporter Program (Kuhn 1988). Further details of the methods are provided in Appendix G. Data from Skeena CWT recoveries were analysed to evaluate stock specific timing patterns in the recoveries. The details of CWT recoveries for each stock, by brood year, by week, by recovery area/gear type are included in Appendix H. Data have been provided for the following rivers: Cedar, Copper, Kitsumkalum, Kispiox, Morice, Bulkley, and Babine. Additional detail is provided for the Kitsumkalum stock giving details by statistical area rather than rolling up into regions.

Although there have been relatively few Cedar River chinook recoveries (45 expanded recoveries for the 8 brood years tagged, Appendix H, Table H 1), the indications from the recovery data (mainly Canadian freshwater sport (BCFW SPORT), suggest a presence of the stock in the lower Skeena River from the April until June. This

corresponds closely with the summary of timing indicated from the 1995 radio tagging program (Alexander and English 1996). The absence of Canadian net (BC NET) recoveries provides indirect evidence that the migration through Areas 3 and 4 were complete prior to the last week of June, which was the normal start date for the net fisheries during the years of adult returns from these brood years.

The Copper River recoveries are sparse for the brood years 1980, 1981 and 1983 (13 expanded recoveries in total), but relatively abundant from the 1984 brood (Appendix H, Table H 2). The timing of the recoveries indicates a presence in the Skeena terminal area beginning in early June but concentrated in the first three weeks of July.

The Kispiox River recoveries (Appendix H, Table H 4) are reported for the years 1980, 1984 and 1987. The recoveries are spread from early June to mid-August. There were 446 expanded tag recoveries reported for BC NET in week 73, however, this result was double checked and confirmed as the information contained in the database.

There are few recoveries (66 expanded recoveries, Appendix H, Table H 6) from the Morice River tagging in 1978 and 1979. The recoveries indicate a presence in the terminal fisheries from May through July.

The Fulton River recoveries from the brood years 1975 and 1978 indicate a presence in BC NET and BC SPORT fisheries from the first week of July until the second week of August (Appendix H, Table H 8).

The Babine recoveries (from 13 brood years between 1975 and 1992) in the BC NET, BC SPORT AND BCFW SPORT catch regions are concentrated from July to mid-August, even in the brood years from the 1970's when troll and net fisheries operated throughout June (Appendix H, Table H 7).

The Bulkley chinook recoveries are mainly from the BCFW SPORT in July, (most of the recoveries are from the Bulkley area sport fisheries (Appendix H, Table H5). The general lack of troll and net catch recoveries from Alaska or Canada indicates a very early run timing before the late June, start of these fisheries.

The Kitsumkalum recoveries for 16 brood years from 1975 to 1992 indicate a terminal migration timing BC NET concentrated in July, with little overlap into June or August (Appendix H, Table H 3). The BC SPORT recoveries suggest the run is also present earlier from the second week of June through the end of July. The BCFW SPORT recoveries are later, from the third week of July to the first week of August, however the sport fisheries are restricted on the start by unfishable water conditions and at the end by a sport closure around the end of July in the sport fishing areas adjacent to the Kitsumkalum.

Additional information is provided for the more extensive data sets for Fulton River, Babine River, Bulkley River and Kitsumkalum River. In addition to the annual information available in Appendix H, the information for all brood years is summarised by catch region, age class and week in Appendix I, and summaries of the weekly recovery distributions by catch region is presented in Figures 12-16.

The Fulton and Babine recoveries in the Alaska (AK) catch region are concentrated from the first week of July until early August and Kitsumkalum recoveries tend to be earlier, from the last week of June to the third week of July (Figure 12). The Canadian troll (BC TROLL) catch region recoveries indicate a similar Babine and Fulton pattern of recoveries throughout July into early August, with Kitsumkalum recoveries earlier, peaking in the second week of July (Figure 13). The timing differences are clearer for the BC NET recoveries which are concentrated from the third week of July to the second week of August, in contrast to the earlier Kitsumkalum recoveries concentrated in the early to mid July period (Figure 14). Bulkley chinook recoveries are sparse, but concentrated in the last week of June and the first week of July. The BC SPORT recoveries indicate an earlier component of the Kitsumkalum (and to a lesser extent Babine) River chinook run not indicated in the BC NET because the fisheries don't operate during this period, and confirm the early run timing of Bulkley chinook (Figure 15). Small numbers of Bulkley Chinook were recovered from the June tidal sport fishery. The BCFW SPORT recoveries show no Fulton and very few Babine recoveries, but indicate a relatively large July harvest of Bulkley chinook (presumably from the upriver fishery in the Bulkley) and a late July early August harvest of Kitsumkalum chinook (mainly in the Skeena mainstem in the Terrace area (Figure 16).

### **Run Timing from GWG REPORT 1980?**

Planning documents created by the DFO Geographical Working Group (GWG) around 1980 included an unreferenced graph that presumably represents the combined wisdom of the time on the Skenna chinook stock specific run timing (Figure 17). This Figure is included out of interest as there are detailed stock specific timings with peak and ranges.

### Skeena Chinook Enhancement

#### Level of Enhancement

Enhancement of Skeena chinook salmon has been modest by regional standards. Total releases in recent years have fluctuated around 500,000 combined fry and smolt

releases (Table 19). Enhancement is predominantly associated with the Terrace, Kispiox, Toboggan Creek (near Smithers) and Fort Babine (outlet of Babine Lake) Community Development Programs. The Terrace area program has tagged 200,000 spring fry annually since 1984 for the Kitsumkalum key stream program, enhances the Cedar River (upper tributary of the Kalum system), and previously enhanced the Copper River (Skeena tributary just upstream of Terrace) and the Coldwater Creek (tributary of the Lakelse River). The Kispiox project has enhanced the Kispiox River since 1979 and a Kispiox tributary, Shegunia River since 1986. Recent releases are in the order of 80,000 to 150,000 fry and smolts annually. The Toboggan Creek hatchery has concentrated on Upper Bulkley chinook enhancement since 1985. Smolt releases have varied widely around an average of 55,000. The Upper Bulkley stock is a CWT indicator stock. The Fort Babine hatchery has enhanced Babine River chinook since 1984. Annual total fry and smolt releases are variable around an average of 45,000. The Fulton River enhancement facility produced chinook fry during the period 1975 to 1979.

### **Survival Rates**

Survival rates for Skeena chinook hatchery releases were estimated from CWT returns as part of a SEP benefit /cost review (data analysis from SEP, Carol Cross, description in Appendix J). Tables of estimated mean brood year survival are included in Appendix J. The Kitsumkalum and the upper Bulkley are true calculations of survival from catch and escapement sampling. Calculations of survival for other releases assume the same escapement proportions as Kitsumkalum or Upper Bulkley. The Skeena chinook survival rates (to brood 1987 release) are summarised in Table 20. The survivals show the expected progression with release type, as spring fry have generally the poorest survivals (average 0.33% n=15), fall fry slightly higher (0.41% n=10), smolts average 0.5 % (n=3) and yearlings 2.0 % (n=7).

Differences in brood year survivals are difficult to separate because of the mix of facilities and release types. Time series of consistent data are present for Terrace spring fry, Terrace yearlings and Cedar 1984 to 1986, however there are no patterns indicating any linkage by brood year in the stock survivals among release types.

### SKEENA CHINOOK HARVESTS

Skeena chinook are harvested in the high seas fisheries, the Alaskan trawl fisheries in the Gulf of Alaska, Canadian and Alaskan troll, seine, gillnet, recreational and native fisheries in tidal waters and Canadian native and recreational fisheries within the Skeena watershed.

# High Seas Fisheries

Healey (1991) reviewed the ocean harvest distribution of chinook and summarised the distribution of the Southeastern Alaskan/British Columbian chinook stock complex as:

"Southeastern Alaskan/British Columbian chinook appear to be relatively rare in both the Bering Sea and the western North Pacific Ocean, at least on the basis of scale analysis. Since virtually all chinook captured in the Bering Sea and western North Pacific are stream type, any fish of the Southeastern Alaskan/British Columbian stock grouping captured there must have been of the stream type race. The Southeastern Alaskan/British Columbian chinook, as well as those from Washington, Oregon, and California, are probably distributed mainly in the eastern North Pacific with the greatest concentrations over the continental shelf waters along the North American coast (Healey 1983). "

Chinook distribution is generally oriented to coastal areas and they are almost never caught in the Japanese squid driftnet fishery (pers. comm. Skip McKinnell).

### Alaskan Trawl Fisheries

The main incidental harvest of chinook in non-salmon fisheries is by the Alaskan trawl fisheries in the northeastern portion of the Gulf of Alaska. Healey (1991) summarises CWT recoveries from 60,000 chinook sampled by observers on foreign vessels and determined that 30.7% were of British Columbian origin out of 244 total CWT recoveries. Skip McKinnell (pers. comm.) provided observed Canadian CWT recovery data from Alaskan trawl fisheries from 1982 to 1994 (Table 21). These data are summarised for all years by release site (Table 22) and for Skeena stocks (Table 23). Tag releases and sampling have been highly variable among years. Skeena origin tags comprise over 5% of the recoveries of Canadian chinook. We were not able to obtain estimates of the total chinook harvest in these fisheries for this review.

# Southeast Alaskan Salmon Fisheries

Southeast Alaskan (SEA) troll, net, sport and probably native fisheries impact Skeena chinook. The Pacific Salmon Treaty (PST) driven management changes in the Alaska fisheries beginning in 1984, delayed the opening of the summer fisheries until July 1 which resulted in the summer chinook troll harvests being concentrated in the first 3 weeks of July. Alaskan chinook harvests have averaged 263,000 (excluding Alaska hatchery production) since the PST was signed in 1985 (which is equal to the Alaskan chinook catch ceiling). The most recent chinook technical report for the 1994 fishing year (Chinook Technical Committee 1996) lists the 1994 SEA chinook catch as

264,300 comprised of 186,300 troll, 42,400 recreational and 35,600 net. The troll catch was divided among a winter fishery (56,400), localised spring terminal fisheries directed on hatchery stocks (11,400) and the main summer fishery (118,500) which lasted for 7 days beginning July 1. Further details of the Alaskan chinook fisheries and harvests are available in the annual chinook reports published by the Pacific Salmon Commission, Chinook Technical Committee for the years 1985 to 1994.

The Skeena chinook CWT fishery harvest proportions by stock, by year are summarised in Table 24. CWT recovery programs are not in place for native fisheries and sport recoveries are opportunistic, with an assumed awareness factor of 4 (observed recoveries are multiplied by 4 to estimate the actual tag recoveries). The data for the Cedar, Copper, Kispiox (and to a lesser extent othert stocks) are sparse in some years and should be interpreted with caution (Table 24). More detailed CWT recovery information is available in previously referenced Appendices H and I. The Fulton (17.3% harvest in Alaska) and Morice (47.5% harvest in Alaska) recovery years were prior to or on the cusp of the PST management changes and represent the best estimate of the pre-PST Alaska harvest proportions. For the more recent CWT recoveries, Alaska harvested only 12.0% of the early migrating Cedar and .7% of the early migrating Bulkley stocks, 29.9% of the Copper, 34.9% of the Kitsumkalum, 8.7% of the Kispiox and 28.3% of the Babine. The average Alaskan harvest percentage, using Kitsumkalum and Babine only is 31.6%.

The detailed CWT recovery breakdown by area for Kitsumkalum reveals the majority of the recoveries from Alaskan commercial fisheries are from the north west area troll fishery (Figure 18) with 74% of the 496 expanded commercial recoveries and the south west area troll fishery with 13.1% of the expanded commercial recoveries. There were 83 expanded recoveries from the Alaska tidal sport fisheries (stocks (Appendix H, Table H9 and Figure 19). The relative contribution of the Alaskan winter troll, and spring hatchery troll fisheries can be estimated from Figure 3. The winter troll fishery (October to April) accounted for 13.5% of the expanded Alaska commercial recoveries of Kitsumkalum chinook, the late May early June hatchery access fisheries accounted for 10.8% of the recoveries.

### Canadian Tidal Fisheries

### **Incidental Harvest in Canadian Trawl Fisheries**

CWT recoveries have been reported for Canadian fisheries, however the data is not organised or readily accessible (Skip McKinnell pers. comm.).

### Troll

The 1985 Pacific Salmon Treaty chinook rebuilding program established an all gear chinook catch ceiling of 263,000 in northern British Columbia. Domestically, this ceiling was initially partitioned with 203,000 to the troll fleet and 60,000 for the combined sport and net fisheries. This was changed in 1989 to gear allocations of 186,000 troll, 42,000 recreational and 35,000 net. The troll catch ceiling is adjusted annually to reflect accumulated catch overages or underages from previous seasons, the troll share of increases to the 263,000 ceiling which occurred in 1989 (39,000) and 1990 (10,000). The management measures implemented to manage the chinook catch to the annual catch ceilings include elimination of the early May-June chinook opening, a delay in the all species fishery until July 1, area closures to trolling (portions of Statistical Areas 10 and 11, and the west coast of the Queen Charlotte Islands in mid-August) and closure of the troll season in early to mid-September to minimise chinook shaking in years when coho are in low abundance. In addition, there is a closure of a large section of northern Hecate Strait after August 25 to reduce the catch of undersize chinook that are relatively common in this area. The chinook harvest may be further reduced in response domestic conservation concerns, as in 1995 and 1996.

Chinook non-retention days in the troll fleet have increased since chinook have been managed to the PST North Coast chinook ceiling of 263,000 (there were zero non-retention days prior to the ceiling closures). The impact of these days is difficult to interpret since the North Coast fishery has been managed to close the areas where chinook are abundant (all of the west coast and a portion of the north side of the Queen Charlotte Islands) once the ceiling is reached. There are still chinook shakers, however the rate of adult encounter is far less than the catch rate in the regular fishing period, although there has been no direct measure. The impact of the chinook non-retention period on Skeena chinook is likely negligible since, almost all Skeena chinook have escaped into the river before the August non-retention period begins.

Troll chinook catch information for Statistical Areas 1-10 combined (Figure 20) and for Statistical Areas 3, 4 and 5 are provided in Appendix K. The chinook harvests in all these fisheries are broad aggregates of chinook stocks and chinook catch trends reflect management actions or coastal chinook abundance more than trends in Skeena chinook.

The Skeena chinook CWT fishery harvest proportions by stock, by year for Canadian troll are summarised in Table 24. There are few recoveries for the Cedar, Copper, Kispiox are most years (and other stocks in some years) which makes the data highly variable. The Morice (26.4% BC TROLL) and Fulton (63.7% BC TROLL) again represent the pre-PST Canadian harvest proportions. The early stocks again had a low relative harvest in Canadian troll fisheries (Cedar 0% BC TROLL and Bulkley 1.7% BC TROLL). The average Canadian troll harvest percentage, using Kitsumkalum and Babine only is 26.9%.

The detailed CWT recovery breakdown by area for Kitsumkalum stocks (Appendix H, Table H9 and Figure 19) indicates the Area 1 troll fishery on average harvested 55.3% of the Canadian troll harvest, with the Area 3 troll fishery taking 36.6% (Figure 20). Please note that the commercial sampling protocol is applied to the aggregate catch region (northern troll Statistical Areas 1, 2E, 2W, 3, 4 and 5 for example) and sampling proportions by statistical area may be inconsistent.

#### **Net Fisheries**

The Skeena chinook CWT recovery patterns by stock, by year for Canadian net recoveries are also summarised in Table 24. There were no net recoveries for the Cedar, but the Canadian net recoveries accounted for an average 11.8% of the annual Bulkley tag recoveries. The net harvests of Fulton stocks averaged 18.2% and for the Morice stock only 5.9%. Canadian net recoveries were 35.4% for the Babine and 35.3% for the Kitsumkalum.

Net chinook catch information for Statistical Areas 1-10 combined (Figure 20) and for Statistical Areas 3, 4 and 5 are provided in Appendix K.

# **Area 1 Seine Fishery**

The Area 1 net fishery on passing stocks, including Skeena sockeye and pink occurred from mid-July to mid-August and was concentrated in the Langara Island region off the Northwest corner of the Queen Charlotte Islands (Figure 20). We use the past tense as the Area 1 Langara seine fishery has been cancelled for 1996 to conserve WCVI chinook. A domestic chinook net catch ceiling of 35,000 was assigned for the North Coast in the chinook reallocation of 1989. The Area 1 and 2W fisheries were each assigned a chinook ceiling of 4,400 and the fisheries were closed if this ceiling is reached.

The detailed CWT recovery breakdown by area for Kitsumkalum stocks (Appendix H, Table H9 and Figure 19) indicates very few recoveries (.9% of the 426 Canadian net recoveries) from Area 1 net fisheries.

### Area 3

Net fisheries occurring in the outer portions of Area 3 (subareas 3-1 to 3-4) target primarily on Skeena and Nass sockeye and pink stocks. Chinook are harvested incidentally in this fishery. Historical weekly effort and chinook catch for Area 3 are provided in Appendix K, Table K 2. The trends in chinook harvest in Area 3 are related more to management actions, fishing effort (based on sockeye and pink abundance) and coastal chinook abundance rather than the abundance of Skeena chinook.

However, the management actions to conserve chinook commencing in 1983 (delay in the season opening from the third week of June to the third week of August) had a positive impact on the Skeena chinook escapements as the seine fisheries were closed during a peak period of Skeena chinook migration through Area 3 (Appendix K, Table K2). The direct benefit for Skeena chinook is not known, but on average (previous 10 years) 44% of the annual Area 3 chinook catch had been taken during the fishing period that was closed in 1983. Recent coastal management changes that caused the whole seine fleet to concentrate in Area 3, and these management actions coupled with very high overall pink and sockeye abundance over the last decade, have resulted in a progressive increase in seine effort in Area 3 (Appendix K, Table K 1). Although some of this increase occurred in August, there has been a 2 to 4 times increase in the 1980's and 1990's effort in the fishing weeks of July, compared to the 1960's and 1970's.

The detailed CWT recovery breakdown by area for Kitsumkalum stocks (Appendix H, Table H9 and Figure 19) indicates the Area 3 fishery harvests 15.0% of the Canadian net harvest.

#### Area 4

The historic development of the Skeena commercial fisheries have been documented by Milne (1955). Sprout and Kadowaki (1987) reviewed the Skeena management system. The Area 4 net fishery is primarily a gillnet fishery which targets on surplus Skeena River sockeye and pink salmon returns. The Skeena River salmon fisheries involve multiple stocks of all salmon species. The commercial fishery is driven by harvestable surpluses of Babine Lake sockeye and area 4 pinks.

The historical pattern of weekly effort and chinook catch for Area 4 are provided in Appendix K, Table K6. This data illustrates the impact of the management actions first implemented in 1972 in response to reduced chinook abundance (Ginetz 1976). There is no direct measure of the harvest reduction on Skeena chinook, but the early gillnet fishery that was eliminated accounted for 21% of the total Area 4 chinook harvest in the previous 10 years. Further restrictions on early gillnet fisheries beginning in 1980 further reduced the Skeena chinook harvests.

In 1992, the Skeena Watershed Committee (SWC), comprised of commercial, recreational, native, provincial and federal government representatives, was formed to address fishery and habitat issues in the Skeena Watershed. The SWC agreed to the following maximum allowable harvest rates for coho and steelhead in Area 4: early coho 19%; early steelhead 33%; and steelhead aggregate 21%. Adjustment to the Area 4 gillnet fishing plan advanced the timing of the fishery earlier to concentrate on sockeye abundance and greatly reduced the fishery in August during the peak of the coho and steelhead runs. The SWC also reintroduced an early directed chinook fishery in 1994. Two, one day, daylight only, fisheries are scheduled annually in June,

with a total catch ceiling of 4,000 (chinook salmon harvests have been well below this level, 1995 hail catch estimate 329).

The detailed CWT recovery breakdown by area for Kitsumkalum stocks (Appendix H, Table H9 and Figure 19) indicates the Area 4 net fishery harvests 84% of the Canadian net harvest of Kitsumkalum River chinook.

### **Skeena Terminal Exclusion**

Canada implemented a program in 1989 to exclude a portion of the terminal chinook catch (chinook greater than 5 lb. in excess of the base period catch of 2,900) in the Skeena, Kitimat and Bella Coola areas. The logic was that the chinook ceilings were intended to cap intercepting fisheries and therefore areas that were purely local stocks should be excluded from the PST ceiling particularly if the local chinook stocks had exceeded PST escapement targets. Initially, a relatively large portion of the Area 4 gillnet fishery was proposed for exclusion, but an analysis of CWT recoveries in Area 4 indicated any fisheries operating outside of the river proper quickly became mixed stock chinook fisheries. The most terminal portions of the Skeena fishery (Figure 11) met these conditions and Canada has subtracted a portion of the terminal area Skeena harvest from the PST ceiling since 1989. The technical details are reported by the Chinook Technical Committee (1991). The terminal area gillnet catches are outlined in Table 25.

Biological sampling programs to confirm exclusion area stocks are of Skeena origin are available from annual reports submitted to DFO (Barb Snyder pers. comm.). The RGS CWT recoveries clearly indicate the RGS exclusion area chinook are predominantly (99.5%) of Skeena origin:

| Year   | Total CWT | Skeena CWT | Non-Skeena CWT |
|--------|-----------|------------|----------------|
| 1991   | 41        | 41         | 0              |
| 1992   | 29        | 28         | 1              |
| 1993   | 13        | 13         | 0              |
| 1994   | 8         | 8          | 0              |
| 1995   | 15        | 15         | 0              |
| Total: | 106       | 105        | 1              |

The stock composition changes quickly in the areas seaward of the river. The Smith Island fishing area (4-12, Figure 11) harvests are a broad mix of chinook from other areas, and the

rest of Area 4 is clearly a complex mix of chinook stocks from Washington, Oregon and British Columbia (J.O. Thomas and Associates 1994).

### FIRST NATION FISHERIES

First nations people have used the Skeena salmon resource for at least 4,000 years (Morrell 1985). Chinook, while not the most abundant food fish in the Skeena river, were important as the first salmon of the season. The current native chinook fisheries include the traditional food, social and ceremonial fisheries in the freshwater and tidal areas of the Skeena. Traditional native fisheries have the first priority for harvesting surpluses after conservation objectives are met. The native fisheries include tidal harvests by drift gillnet and seine during periods when the commercial fishery is closed, and in freshwater, dipnet, setnet, gaff, drift gillnet and more recently beach seine, fishwheel and weir harvests. In recent years, allocation agreements have been signed as part of the Aboriginal Fisheries Strategy (AFS) fishery agreements. The Skeena River allocations for 1995 are summarised in Table 26.

There are First Nation, excess to salmon spawning requirement (ESSR), fisheries in the Skeena for sockeye and pink, using selective harvest techniques, but chinook are not included in these arrangements as a surplus has not been established for any chinook stock.

### **Tsimshian**

The Tsimshian Tribal Council represents member bands (Metlakatla, Lak K'waalams, Kitkatla, Kitsumkalum, Kitselas and Hartley Bay) with population centres in Metlakatla, Port Simpson, Kitkatla, Terrace area, Hartley Bay and a large off reserve population in Prince Rupert (Figure 21). Traditional Section 35 (meaning native fishing rights described in Section 35 of the Canadian Constitution) fishing is conducted in the vicinity of all villages and in tidal approach waters using commercial gillnet and seine gear and in the Skeena River up to Lorne Creek Figure 22 using set and drift gillnets and more recently, fishwheels.

#### Gitksan-Wet'suwet'en

The Gitksan-Wet'suwet'en bands (Kitwanga, Kitsegukla, Gitanmaax, Hagwilget, Glen Vowell, Kispiox, Kitwancool and Moricetown) are represented by the Gitksan-Wet'suwet'en Watershed Authority (GWWA). These bands are all associated with a village of the same name (Figure 22). Section 35 fishing is currently conducted in the Skeena River upstream of Lorne Creek, in the Babine River to Kisgagaas, and in the Bulkley River. The bulk of the harvest is taken by setnet in the Skeena, Bulkley and Babine Rivers. In the Moricetown canyon, gaffing and dipnetting are the most common harvest method. Palmer (1987) provides an extensive review (63 pages) of the

evolution of the Gitksan-Wet'suwet'en traditional fisheries from 1868 to 1984. Morrell (1985) describes the Gitksan mainstem Skeena chinook fishery,

"In spring, as soon as there are large stretches of open water on the Skeena, a few individuals begin fishing with drift gillnets. This early fishery targets first on pre-spawning steelhead and later on chinook salmon. This fishery begins in the lower reaches of the Skeena and spreads upriver as conditions permit. From late April through June a few large mesh set nets are fished for steelhead and early chinooks. Catches in this spring fishery are low in most years, and fishing conditions are difficult due to rising water and drifting debris. ... The first sockeye reach Gitksan territory in late June or early July, along with the main body of the chinook run. This marks the beginning of the major summer set net fishery."

#### **Lake Babine Nation**

The Lake Babine Nation has villages located at Fort Babine, Topley, Old Fort and Burns Lake. The Section 35 fishery occurs mainly in Nilkitkwa Lake and to a lesser extent in Babine Lake (Figure 7).

#### Takla Lake Band

The Takla Lake Band is represented by the Carrier-Sekani Tribal Council and their village is located in Takla Lake (located approximately 50 km east of Fort Babine). Their fishery takes place on Bear River and Lake and on the Sustut River.

### **Yechooche Band**

The Yechooche Band also belongs to the Carrier-Sekani Tribal Council. Their harvest occurs on Babine Lake in the vicinity of the Sutherland River, and consists entirely of sockeye.

### **First Nation Chinook Catches**

First Nation chinook harvests are summarised in Table 27 and include: the current DFO records from 1951 to 1995 by subarea, estimates for total Area 4 from 1925 to 1950 (Argue et. al. 1986), and Moricetown (1930 to 1983) and Hagwilget (1929 to 1962) catch records from Palmer (1987). The catch estimates from all sources represent compilations of DFO historical records of First Nation harvests from guardian and Fishery Officer observations. These records presumably give an indication of the relative magnitude of the harvests but generally the information is available only as annual summaries with no documentation of survey areas, effort or specific

methodologies. Even the most recent estimates are uncertain because of changes in the DFO fishery officer effort to collect the data, and because some of the recent information is from First Nation catch reporting initiatives that have not been evaluated or compared to the historical DFO methods.

Catch reporting areas do not always facilitate separating First Nation chinook catches by Band or Band aggregates, or by river system. The Tsimshian chinook harvests are best indicated by the DFO records for the lower Skeena plus the Terrace area after 1979. The lower Skeena chinook harvests represent 16%, and the Terrace area, 9%, of the Skeena Section 35 harvests for 1980 to 1995. The Gitksan-Wet'suwet'en catches are generally represented by the Hazelton and Smithers reported catches after 1979, and they represent 52% (Hazelton) and 26% (Smithers) of the Skeena chinook harvests for 1980 to 1995. The Smithers catch includes a relatively small number of chinook harvested by the Babine Lake First Nation.

The Gitksan-Wet'suwet'en estimated chinook harvests in their area in 1985 to be between 7,797 and 9,736 (Morrell et al. 1985). This compares closely to the fishery officer estimate of 10,300.

# **Sport Fisheries**

### **Tidal**

Important recreational fisheries that concentrate on chinook in the early season occur in the tidal areas adjacent to the Skeena. The Area 3 and 4 recreational fishing effort and chinook catch by subarea for 1995 (Figure 23) is outlined in Table 28. The chinook fishery is quite diversified, however in Area 4 effort directed at catching chinook is often concentrated in Edye Pass (Subarea D) and the northern tip of Stephens Island (Subarea F). The majority (80%) of the recreational fishing trips in 1995 were unguided based on the interviews conducted as part of the 1995 creel survey (J.O.Thomas & Associates 1995). The creel survey accurately reflects the Area 4 proportions, but underestimates the contribution of fixed station lodge operations operating in Area 3 that were not sampled at the interview sites.

Historical recreational catch data for chinook in Area 4 is summarised in Table 29. The data is a summary table maintained by DFO, Prince Rupert from historical fishery officer and guardian reports. The methods and reporting are inconsistent and the data is best used to indicate general trends. The only data of known reliability is the 1995 creel survey of Area 4 and a portion of Area 3 conducted from May 15 to September 15, 1995. A total of 1,053 interviews were taken from an estimated 6,262 boat trips. The chinook catch estimate totalled 1,995 (1,540 were taken in Area 4). The estimate is lower than many recent years however the chinook fishing was reported to be very poor in 1995 (Steve Cox-Rogers, pers. comm.).

The Skeena chinook CWT fishery harvest proportions by stock, by year for Canadian tidal sport fisheries are summarised in Table 24. The Morice (12.3% BC SPORT) and Fulton (0.9% BC SPORT) again represent the pre-PST Canadian harvest proportions. The BC SPORT harvest proportions for other stocks were Cedar 7.1%, Copper1.7%, Kitsumkalum 6.4%, Kispiox .3%, Bulkley 17.9% and Babine 1.9%.

The detailed CWT recovery breakdown by area for Kitsumkalum stocks (Appendix H, Table H9 and Figure 19) indicates the Area 1 tidal sport fishery on average harvested 55.3% of the Canadian tidal sport harvest, and the Area 4 sport fishery taking 41.3%.

### **Freshwater**

The Skeena River supports an important river recreational fishery for chinook and other salmon species. The most intensive chinook fishery is concentrated in the lower Skeena River mainstem in the 100 kilometres below Terrace, but other chinook fisheries occur on the Kitsumkalum, Kispiox, Babine and Bulkley Rivers in addition to the Skeena mainstem upstream of Terrace and the tributaries of the lower Skeena.

Historical recreational catch data for chinook is summarised in Table 29. Subarea catch reports (from guardian and fishery officer annual records) available up to 1991 indicate the Terrace area was the major recreational fishing area, followed by Smithers, Hazelton and finally the lower Skeena.

There is little creel survey data available for the Skeena freshwater recreational fisheries. The results of the 1995 creel survey (Tallman 1995) of the Lower Skeena River (Figure 24) recreational fishery are summarised in Table 30. The chinook catch estimate for 218, 142 angler hours was 2,784 (jacks and large not separated). Local anglers comprised 50% of the fishers interviewed of which 16% were guided.

The only previous detailed creel survey in the Lower Skeena freshwater recreational fishery was in 1984 (O'Neill and Lewynsky 1985). For the period July 1 to October 15, 1984, 76,334 angler hours (10,602 angler days) were expended to capture 499 large chinook and 1,791 chinook jacks. In comparison to the 1984 study, local anglers comprised 57% of the fishers interviewed of which 14% were guided.

In the lower Skeena freshwater recreational fishery in 1995, Tallman (1995) reported 2 adipose clipped chinook were observed from a sample of 134 fish (mark incidence 1.5%). A total of 5 CWT recoveries (from an estimated catch of 2,784) were voluntarily submitted from the survey area by recreational fishers. Since 42 returns would be expected if the compliance rate was 100% and the recreational catch was marked at the same rate as the observed sample, this data indicates a submission rate of 11.9% from voluntary returns. If this is true, the MRP standard expansion of 4 would be an underestimate for this Skeena freshwater fishery.

The Skeena chinook CWT fishery harvest proportions by stock, by year for Canadian freshwater sport fisheries are summarised in Table 24. The BCFW SPORT harvest proportions were Cedar 72.3%, Copper 30.4%, Kitsumkalum 3.4%, Kispiox 0.0%, Bulkley 68.0%, Morice 7.9%, Babine 1.9% and Fulton 0.0%.

### DISCUSSION

### **Escapement Accuracy**

Shardlow et al. (1987) demonstrated that visual counts underestimate the actual number of salmon present. This is consistent with the evaluations for surveys of large terrestrial animals (Caugley 1974) and marine mammals (Eberhardt et al. 1979). Sockeye counting fences on the Sustut and Johanson Lakes, installed in 1993 resulted in sockeye escapement estimates 5 and 10 times the recent DFO averages (pers. comm. Ken Shortreed). A study of the 1992 chinook escapement to the Nass River system found the actual escapement was 2.3 times the DFO escapement estimate of 6,730 (Koski et al. 1993). The study determined that the Bell-Irving system was the single largest chinook spawning area. Previous spawning estimates for the Bell Irving had been zero (because of the turbid water conditions). The extent that the Skeena chinook escapement estimates are underestimated is not known but there is the potential for significant underestimates. The Skeena escapement record is not believed to provide an accurate assessment of the absolute chinook escapement with the exception of the Babine Weir, Kitsumkalum mark recovery and the Upper Bulkley Weir programs.

The Skeena test fishery and the Fishery Officer visual estimates are believed to provide useful indices of escapement. This is based mainly on the correlation between the Skeena test fishery chinook indices and an index of Skeena Fishery Officer escapement counts which were demonstrated by Riddell and Snyder, (1989) to be significant (but explained only 36% of the variation in observed escapements). The relationship between Babine escapements and the test fishery index to 1988 was not significant because the large increases in the test fishery index in the years 1984 to 1988 were not reflected in the Babine data (Riddell and Snyder 1989). There has been a relative increase in the Babine escapements from 1989 to 1993, but a severe drop in 1994 and 1995. In general, the Babine escapements have not varied in parallel with the Skeena test fishery or the overall Fishery Officer escapement estimates. The plots of individual stream chinook escapements in Figure 6 illustrates there is a lot of variation among streams although there are no patterns by size of stream, or by geographical subareas (Figure 5).

There is a need to document and calibrate chinook escapement methods for the Skeena.

# **Bias in Biological Sampling Techniques**

Biological data for the Skeena watershed is available from a wide variety of sources. Methodologies for collecting the samples varies widely and are often not fully documented. Adult age, size and sex structure are particularly susceptible to the bias introduced from different sampling methodologies. All sampling methods likely have a bias, and few have been evaluated and documented. An important source of biological samples for Skeena chinook are from the Skeena test fishery which has a well documented salmon size bias (Kadowaki 1985) and Figure 25 (from Cox-Rogers and Jantz 1993). This bias results from larger fish being susceptible to capture in more panels of the test net since large fish can tangle in small mesh but small fish rarely are caught in larger mesh sizes. The effect for chinook would be expected to be far more pronounced than for sockeye. This would skew the biological data collection to the older/larger chinook. This problem may be further exaggerated because the smallest chinook sizes would have a low catchability in the test net (minimum mesh size 3.5 in, 8.9 cm mesh). A test fishery using a seine boat was operated in 1988 and the age structure from the biological samples indicates a much higher proportion of younger age classes, although this is also not believed to be a representative sample as the gear was not able to capture large chinook (Les Jantz, per. comm.).

Biological samples from Skeena tributary carcass recovery programs should generally be representative, although the assumption that the availability of carcasses does not vary with size and sex requires evaluation. There is an undersampling of chinook jack at the Babine Fence in some years because the smaller chinook carcasses are mixed with very large numbers of similar size pink salmon, all in various stages of decomposition, and in recent years an increased number of chinook carcasses are removed by grizzly bears (Mike Jakubowski, pers. comm.). Brood stock collections, another common source of biological samples, are often biased by the gear, time and areas where the collections occur. Another general problem with data analysis is the samples should be taken, or at least evaluated, based on a weighting in proportion to the abundance at the time of the sample. This was not done for any of the evaluations in this report, mainly because the data is not readily available, with the exception of recent years for the Skeena test fishery.

# **Accuracy of Chinook Age Determination**

Although both the Vancouver and PBS scale labs have careful documented approaches to chinook age determination, the methodologies for scale reading appear to rely on subjective expertise to determine both the freshwater and total age for chinook. The summary of chinook life history information by Healey (1991) referenced Skeena age structure data (48.1% stream type) published in Godfrey (1968) and Ginetz (1976). This indicates either a lack of knowledge or the lack of acceptance of

the current scale age interpretations that have been in effect since 1980. There is a need to provide a consistent scale interpretation based on calibrated techniques, perhaps used fin rays or CWT chinook to verify ageing.

## Relative Brood year Strength at the Test Fishery

The Skeena River test fishery annual chinook age proportions were multiplied by the annual test fishery index to create relative indices of abundance for age 4, 5 and 6 year old chinook (Table 31). The jack index was used to represent the jack abundance since the sampling data for 2 and 3 year old chinook was inconsistent. The results are presented in Figure 26 which has been adjusted so that the returns at age from any brood year line up vertically to allow for easier comparison of whether relative brood year strength is consistent across age of return. The data clearly indicate a failure of the 1985 brood year that was first evident in the jack index of 1988 and carried forward in the relatively poor returns of the brood in 1989, 1990 and 1991 (Figure 26).

We tested the relationships between the jack index and the subsequent 4 year old returns the next year, and the 4 to 5 and 5 to 6 year old sibling comparisons. The regression results indicated:

|        |    |                        | R-  | ٢     |
|--------|----|------------------------|-----|-------|
| Figure | 27 | Jack predicting age 4  | .30 | .033, |
| Figure | 28 | Age 4 predicting age 5 | .48 | .004, |
| Figure | 29 | Age 5 predicting age 6 | .46 | .006. |

Forecasts using the regression relationships suggest 1996 abundance as follows:

| 4 year old contribution | 20.9  | index points, |
|-------------------------|-------|---------------|
| 5 year old contribution | 79.7  | index points, |
| 6 year old contribution | 38.7  | index points, |
| Total                   | 139.3 | index points. |

An index of 140 would be higher than the 1995 index of 113.8 but lower than the 175.7 index of 1994 and the 196.9 index for the 10 year average (1986 to 1995). The data indicate there has not been a dramatic shift to lower production levels as is evident for WCVI stocks. The drop in the jack index in recent years is of concern, however the relationship between this index and the subsequent return of 4 year olds is poor, an example being the moderately high index for 1995 4 year olds in contrast to the poor 1994 jack index.

## **Terminal Run Timing**

The analysis of aggregate Skeena chinook run timing all support a terminal area peak migration past the test fishery during the first 10 days of July and a general chinook

abundance spanning the second week of June until the fourth week of July. The extended period of chinook abundance is presumed to result from a series of individual chinook runs that peak from mid-June until mid-July. The Skeena management model uses a normally distributed chinook run timing with a peak of July 5 (at Tyee test fishery) and a standard deviation of 12.5 days (Figure 30, from Cox-Rogers 1994). The evidence in this report indicates a timing proportion curve that reflects this flat timing distribution would better represent the Skeena chinook timing in the terminal area. The previous unreferenced chinook migration timing in Figure 17 corresponds well with the determinations of stock specific timing in this report. Stock ID methodologies under development represent the best opportunities to resolve Skeena chinook stock specific timing.

#### **Skeena Chinook Harvests**

#### **High Seas Fisheries**

The harvest of Skeena chinook in the high seas fisheries does not appear to be an important issue because catches are believed to be very low.

## **Alaskan Trawl Fisheries**

We did not obtain information on the total chinook harvest or the CWT sampling rates in the Alaskan trawl fisheries. We do not know what information is available.

#### **Terminal Run Size and Harvest Rates**

Terminal Skeena River chinook abundance is summarised in Table 25. The terminal harvest rates (excluding RGS) have been generally stable over time. Assuming the information in Table 25 is correct, the 1966 to 1983 average harvest rate of 26% is the same for the more recent period 1984 to 1995. During the last two years when overall abundance has declined the harvest rate were essential unchanged indicating terminal fisheries take a fixed proportion of the chinook run seemingly independent of run size. If the RGS chinook catch is added the terminal harvest rate increases to an average of 34% for the period 1984 to 1995 again with no apparent trends. The total terminal chinook run (including RGS) catch ranged between 50,000 and 109,000 with an average of 83,600 (1984 to 1995).

#### **Skeena Model Analysis**

The Skeena Model (Cox-Rogers 1994) although specifically designed to analyse sockeye, coho and steelhead harvest rates under various fishing scenarios also gives an estimate of a relative chinook harvest rate index. The key model assumptions include a chinook peak migration timing entering the Area 4 fishery July 1, a normally distributed run timing curve (S.D. 12.5 days) and chinook catchability equal to sockeye.

Indicated harvest rates should be considered only as indices, particularly given the untested assumption of chinook catchability equal to sockeye. The Area 4 harvest rate indices for various model runs are indicated below:

| Year              | Harvest Rate<br>Indicator |
|-------------------|---------------------------|
| 1986-1991 Average | .20                       |
| 1994 Pre-season   | .28                       |
| 1994 Post-season  | .22                       |
| 1995 Pre-season   | .31                       |
| 1995 Post-season  | .28                       |
| 1996 Pre-season   | .33                       |

Model analysis indicates recent changes to the Area 4 gillnet fishery have increased the chinook harvest rate index, mainly because of the shift to an earlier timing in the fishery, and to a very small extent from the directed chinook fishery. This shift represents a significant increase in terminal chinook harvest rates that should be considered in future management decisions, particularly given the lower chinook abundance of 1994 and 1995.

## **Exploitation Rate Analysis**

The calculations of ocean exploitation rates for Kitsumkalum and upper Bulkley chinook stocks are presented in Table 32 (derived from SEP data Appendix J). The last complete brood year is 1988 since the 1995 escapement information has not been entered into the SEP database. Native harvest estimates are not included, because of the lack of CWT recovery. The total exploitation rate averaged 48% (45% ocean) for Kitsumkalum and 16% (11% ocean) for upper Bulkley chinook. The Alaskan proportion of the total exploitation averaged 18% for Kitsumkalum and 0% for Bulkley chinook. The Canadian commercial proportion of the total exploitation averaged 24% for Kitsumkalum and 2% for Bulkley chinook. The Canadian tidal sport proportion was 3% for Kitsumkalum and 1% for Bulkley. The Skeena freshwater fisheries took 2% of the Kitsumkalum chinook and 11% of the Bulkley. The Terrace area tag return rate for 1995 was estimated to be 11% from the 1995 creel survey, and 25% is assumed for this analysis. The Upper Bulkley awareness factor is unknown.

Hankin and Healey (1986), suggested probable MSY exploitation rates for midmaturing stocks (like the Skeena) of 40 %. Even without the native harvest factored in, the exploitation rate on Kitsumkalum chinook is above this level.

Hankin and Healey (1986), predicted sex specific age composition of chinook under unexploited and on the verge of collapse (Figure 31, from Hankin and Healey 1986). Skeena River stocks were used as an example of mid-maturing stocks. Comparing the Skeena test fishery data (Table 8) the recent sex specific age structure indicates there is not a clear match. The Skeena data does not fit the mid-maturing chinook stock type as the proportion of age 6 females are higher than the age 5 (more towards a late maturing stock). The male age distribution for the Skeena is spread almost evenly among the age 4, 5 and 6 chinook, which suggests more of a late maturing schedule. We could not conclude whether the Skeena chinook age structure pattern best fit the stock at collapse or the unexploited equilibrium. Possibly the Skeena stocks are an aggregate of maturation types, or the test fishery provides a biased sample of the escapement.

#### **Productive Potential**

## **Trends in Stock Productivity**

The survival information from the analysis of SEP chinook releases in the Skeena was too variable to indicate trends or even weak or strong brood year survivals (Table 20). The increase in chinook escapement to the Skeena that occurred coincident with the PST management measures is generally attributed to reduced ocean harvests. There are no Skeena exploitation rate indicators that represent the before and after so there is no technical confirmation to rule out another plausible explanation that there was a concomitant increase in survivals. The Fulton survivals from spring fry releases (1975 to 1979) suggest an increasing trend in survivals beginning in the 1978 brood that would result in increased escapements beginning in 1982 with much larger escapements expected in 1983 and 1984 (Table 20). The shift in the terminal area run timing associated with the PST management actions does not support the theory of a general increase in productivity as the explanation for the increased escapements in the early 1980's, because a shift in productivity should affect all segments of the run equally and there should be no timing shift.

## The Salmon Treaty Experiment

If reduced harvest rates caused the increase in escapements coincident with the PST management measures and this reduction was maintained (the management scenarios have been stable) the large escapements of 1986, 1987 and 1988 should produce a test of whether the escapement levels in 1986 to 1988 have reached optimum levels. If the escapement levels are still well below optimum and the fishing and productivity regimes remain stable, a large increase in escapement would be expected in the return

years 1991 to 1993. This increase did not occur and escapements were stable or slightly lower. Given the assumptions in this test, the conclusion was the aggregate Skeena chinook stock is at or above optimum escapement level. The fisheries management regime for chinook has changed little during the period in question and the fishery exploitation rates appear to be relatively stable. The validity of the assumption of a stable ocean environment is unknown. As discussed previously the hatchery release survival data is a mix of release types and determining survival trends is not possible. If escapement levels were well below optimum and ocean survival of chinook decreased, the observed trend in escapements could result.

#### **Historical Production Levels**

Riddell and Snyder (1989) reviewed historical Skeena chinook production estimates and concluded it was plausible the Skeena chinook catch peaked at up to 150,000. A draft report by Argue suggests even greater values, well over 200,000 for decade high average catches (pers. comm. Sandy Argue).

## **Target Escapements**

There are no biologically derived escapement targets for Skeena chinook. The basis for the interim target of 41,770 established in the Pacific Salmon Treaty process is to double the baseline 1979 to 1982 escapement over the 15 year course of the rebuilding program. The objective was met for the Skeena from the first year of the rebuilding program and has exceeded this rebuilding target each year from 1995-1994 (Figure 32, Chinook Technical Committee 1996). The 1995 escapement was slightly below the PST target.

Fishery Officers assigned escapement targets to each Skeena tributary based on subjective evaluations of spawning ground capacity. These escapement targets total 99,610 (Table 33). There is no way to assess the accuracy of these target escapements and they are no longer in use, other than to provide one indication of the general magnitude of the productive potential.

#### Stocks of Concern

The overall escapement increase in response to the Pacific Salmon Treaty (PST) management changes beginning in 1983 are evident in the overall escapements and in each subarea escapement pattern (Figures 4, and 5). However, Figure 6 illustrates that all Skeena chinook stocks did not increase during this period and of those that did, many returned to relatively low levels in 1994 and 1995. Further research is required to document specific systems where escapements have declined significantly from historical levels.

## **Upper Bulkley Chinook**

Although the Upper Bulkley chinook stock appears to have an extremely low ocean harvest rate, there are still concerns over the total exploitation rates. Milne (1950) observed during the years 1945 - 1947 that 35% of the salmon gaffed at Moricetown were lost in a damaged condition. Harding (1969) reports 44% of the salmon gaffed in the 1967 Moricetown fishery were lost. Palmer (1964) also observed over several years that virtually no gaff injured sockeye reach the spawning grounds. Mike O'Neill (pers. comm.) also reported that chinook observed in the Upper Bulkley very rarely show any gaffing injuries and makes the inference that injured chinook do not make it to the spawning grounds. The estimate for Moricetown chinook harvests in a 1990 study (Mike O'Neill, pers. comm.) were a native harvest of 7,247 and an associated mortality of 7,267 for a total mortality of 14,523 chinook. The reported chinook escapement for systems above Moricetown was 12,300 giving a Moricetown fishery an estimated harvest rate of 54.1%. The Moricetown fishery harvests a mix of stocks and the Bulkley River probably represents a small proportion of the chinook harvests (Bulkley escapement in the 1980's was 5% of total Bulkley and Morice subarea).

The escapement, native harvest (adjusted for gaffing mortality) and estimated harvest rate for chinook at Moricetown for the period 1951 to 1963 (Table 34) was calculated by Palmer (1964). The estimated average chinook harvest rate for the period was 24.9 percent. DFO record keeping methods have changed and we could not locate Native catch records specific to Moricetown, so we did not upgrade the table to include the more recent time periods. Harding (1969) reports a 15% harvest rate on chinook at Moricetown in 1967. This appears to be based on the tagging of 224 chinook below the falls at Moricetown. Subsequently, 26 were returned by Natives and 5 were observed on 237 fish which used the left bank fishway. These numbers indicate a Native harvest rate of 11.6% and a chinook escapement past Moricetown of 10,618. There is no information provided to access the proportion of the Native caught tags that were recovered, tagging mortalities, or other assumptions. The author does note that the early portion of the chinook migration was missed in the sampling.

Significant progress in communication regarding the Moricetown chinook harvest has occurred in the SWC. Continued progress is important to assess this potentially large harvest impact.

During the planning of the Area 4 June directed gillnet chinook fishery, the SWC expressed concerns that the fishery may harvest some Bulkley chinook. Chinook samples (approximately 30% of the 1995 RGS gillnet fishery catch of 329) were taken for GSI analysis to identify the proportion of upper Bulkley chinook in the early June chinook fishery. Bulkley chinook are very distinct and easily separable from other Skeena stocks (Chris Wood pers. comm.). The samples have not yet been analysed.

#### **Cedar River Chinook**

This stock is a concern in part because of the low escapement numbers and a local targeted recreation fishery, even though there has not been a major decrease from historic reported escapements. The Cedar River chinook issue is being addressed by the local recreational community as a result of the Skeena Green Plan radio tagging study.

#### **Babine River Chinook**

Babine chinook need to be considered more closely as a stock of concern given the particularly low escapements is the last 2 years and the possible impacts of the net management changes. The outside fisheries in Alaska, particularly the troll fisheries, were greatly reduced in June, but intensified in the July period which would impact the late timing Babine stock more than the earlier Skeena chinook stocks. Similarly, the British Columbia troll harvest is now concentrated during July and is coincident with the Babine chinook timing. The Skeena-Nass net fisheries have also concentrated their harvests from July 10 to August 10 which would be expected to differentially impact the later migrating Skeena chinook stocks.

#### Stock ID Potential

Stock specific information from the test fishery and commercial catches is essential if chinook management is to become more stock specific. Research on chinook stock identification techniques is underway on a number of fronts. Data from chinook GSI allozyme research conducted by the National Marine Fisheries Service indicates potential for chinook stock separation within the Skeena River for certain stock aggregates (Figure 33 from David Teel, NMFS pers. comm.) Additional information provided GSI analyses of mixtures of known composition. However the trials grouped Skeena stocks as follows: Group 1. Bear-Babine-Morice: Group 2 Kispiox-Kitwanga: Group 3 Kitsumkalum-Cedar: and Group 4 Bulkley. The analyses indicated estimated proportions deviated from 0% to 5 % from the true proportion. We are not clear whether these groupings represent the results of trials to determine the groupings that give the best definition. The technique is of interest even at the levels of definition indicated although the Bear Babine Morice aggregation combines three of the four largest Skeena stocks.

Beacham et. al. (1996 in press) evaluated geographic variation in chinook minisatellite DNA. Estimates of stock composition from simulated mixtures within the Fraser and Skeena drainages were accurate and precise, suggesting that discrimination among stocks within river drainages may be possible (Table 35).

Two additional research programs evaluating microsatellite DNA and laser ablation techniques for differentiation of Skeena chinook stocks are currently being sponsored

by the Skeena Green Plan for 1996 to 1997 (Chris Wood pers. comm.). The DNA and laser ablation methods are particularly useful for assessments since archived scale samples can be used for historic stock specific assessments.

#### Skeena Chinook PSARC Recommendations 1989

The recommendations for Skeena chinook presented in PSARC paper S89-18 (Riddell and Snyder 1989) were as follows:

Achievement of maximum biological yield from the Skeena chinook stock is unlikely to be a realistic management objective in the near to medium term. It is recommended that the requirements of the various users be identified and a stock management plan developed to meet these needs while more quantitative information is collected. Specifically, an information system should involve:

- 1) Establishment of a harvest sharing policy for terminal runs in excess of the interim escapement goal. This policy would include a set of rules, agreed to by the user groups and the Department, on how to utilise large returns to increase fishing opportunities and also evaluate production from spawning escapements larger than the interim goal. A fixed harvest rate on returns above a minimum escapement level is suggested as a policy to evaluate.
- 2) Annual biological sampling of the escapement in specified populations to provide data on variation in brood year survival, age composition of the separate populations, age at maturity by sex, and biological traits useful for stock identification. Hankin and Healey's (1986) analysis clearly indicates the necessity of collecting age composition and maturity data in chinook populations. Without this information we will not be able to assess the biological productivity of Skeena chinook.
- 3) Priorization of the streams to be monitored for escapement so that the streams which have been consistently surveyed continue to be annually monitored, and in a standardised and reproducible method. Included in this priorization must be a process for collecting the data recommended in point (2).
- 4 A program should be developed to investigate the stock structure of Skeena River chinook salmon. This program will be essential to developing an appropriate escapement goal for the Skeena system. The program should initially evaluate how to discriminate between spawning populations and collect basic age composition data. At present in the chinook rebuilding program, Skeena chinook are treated as a single aggregate stock. However, the differences in escapement recoveries between stream since 1984 suggest that the populations do function independently from each other and that there may therefore be discrete stocks. At least the populations within major runtiming segments should be identified.

5) The Skeena River test fishery should be conducted earlier to collect data on run timing, abundance, and biological samples. How early the fishery might start is uncertain and will likely require some experimental fishing. This will be particularly important if terminal fisheries on increased returns of chinook are anticipated. During evaluation of when to start fishing, the number of weeks to be monitored could be increased by reducing the number of days fished per week.

#### Action on the 1989 PSARC Recommendations

- 1) The SWC allowed a directed gillnet fishery to be initiated in 1994, in part based on the PSARC assessment that a harvest on stocks above the minimum escapement level was appropriate. Perhaps a bigger impact resulted from the SWC management plan to conserve coho and steelhead by fishing earlier and harder on the sockeye while greatly reducing the fishery on the later run coho and steelhead.
- 2) Sampling programs at the Skeena test fishery and Babine Weir were improved and the data reported and analysed in this report. Tributary biosampling other than the Babine was not conducted because of fiscal restraints. Even if we collected this information as requested in the 1989 recommendation 2, we would not be able to assess the biological productivity of the Skeena chinook as previously stated.
- 3) This recommendation was achieved in the Skeena for 1995, mainly as a result of the retooling required after the fishery officer reorganisation of 1993. Further efforts are required to improve the standardisation and documentation of the escapement programs.
- 4) As reported in this document considerable research effort has been applied to developing a stock identification methodology for Skeena chinook. Results will be reported over the next year, but initial indications are that a number of effective methods of stock separation will be available.
- 5) The Skeena test fishery was not started earlier as the test fishery continues to have shortfalls in payment fish and has required large subsidies in some years. Payment fish and operating shortfalls continue as an issue in 1996 and may result in the cancellation of the chinook portion of the test fishery after 1996.

#### **PSARC** Recommendations

- a) The Skeena biological database initiative developed as part of the Skeena Green Plan initiative should be completed, documented and maintained in future years.
- b) The Skeena Test Fishery program should be expanded to collect age, length, sex and appropriate tissue samples for all chinook captured in the test fishery including all small chinook 'jacks'.
- c) The Babine Counting fence sampling program should be expanded to sample all carcasses recovered and an assessment be conducted of the proportion of the jacks sampled.
- d) A documented review and database development for the historical sport catch figures for the Skeena and adjacent areas is necessary to qualify the information currently in use.
- e) Native catch figures are currently provided through the AFS programs. We need to review the historical data and use the expertise of the first nations people to reconstruct catches, and to evaluate the current enumeration programs.
- f) The current Skeena chinook escapement monitoring program must be evaluated and documented in conjunction with the broader based DFO stock assessment stock assessment initiative to rationalise all aspects of the escapement program on a regional basis.
- g) An evaluation of the chinook ageing standards should be a priority of the new amalgamated scale lab.
- h) Data on the harvest and CWT mark rate in the Moricetown First Nation fishery is essential to evaluate the exploitation rate for the Upper Bulkley chinook exploitation rate indicator. Estimates of First Nation, and recreational chinook harvests are required to assess the impacts of these terminal fisheries on the Upper Bulkley chinook stocks. Significant progress in communication regarding the Moricetown chinook harvest has occurred in the SWC. Continued progress is important to assess this potentially large harvest impact on a stock of concern.
- i) Impact on chinook stocks should be considered as part of the development of the Skeena Area 4 gillnet fishing plan as well as other outside and terminal fishing plans.
- j) The Skeena chinook assessments and management should continue to evolve towards more stock specific management. Stock identification programs for chinook are essential and the research program associated with the Skeena Green Plan should be pursued as a priority.

k) We are not able to recommend a biologically based escapement target, or exploitation rate target. The Pacific Salmon Treaty escapement target seems to represent a very conservative risk adverse escapement floor. The terminal fisheries on the Skeena currently seem to harvest at a fixed harvest rate. This allows for increased chinook harvest during periods of high abundance. Taking into consideration this pattern, there is also the potential for modest increased exploitation on escapements well in excess of the PST rebuilding target, consistent with PSARC recommendation 1 in 1989.

FIGURE 1. MAP SHOWING THE SKEENA RIVER WATERSHED AND ADJACENT CANADIAN AND U.S. FISHING AREAS.

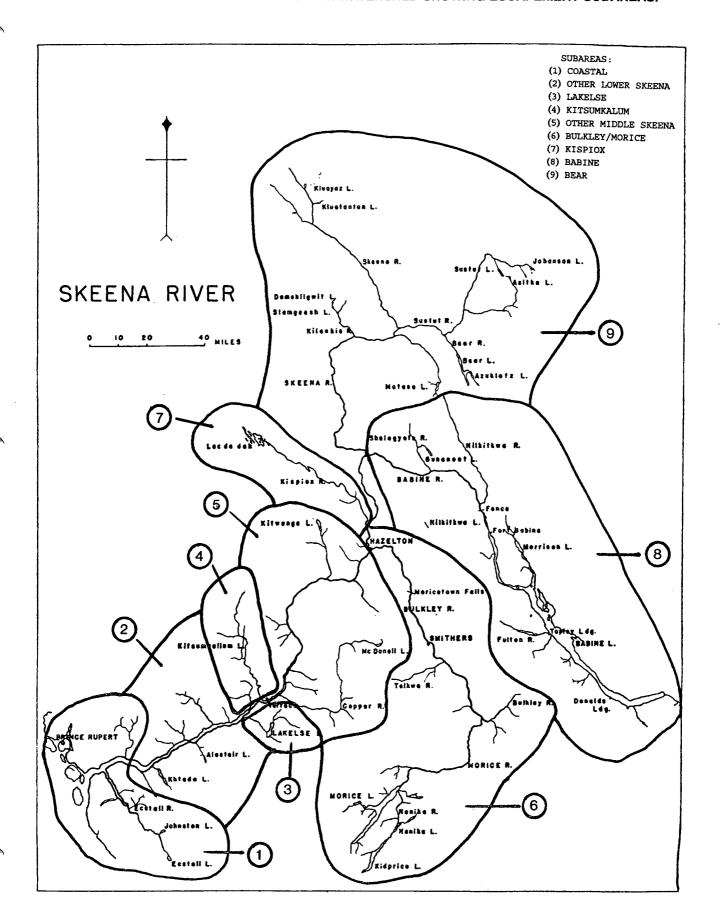

#### FIGURE 2. PICTURE OF A LARGE CHINOOK SALMON.

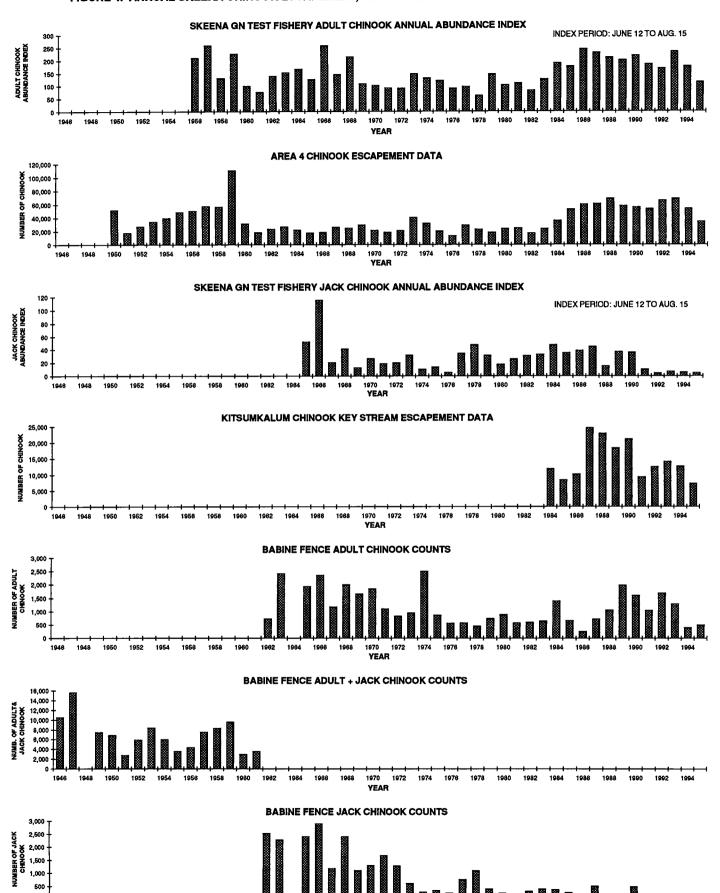

This male chinook was measured at 55 inches long with a 38 inch girth, which equates to 105 pounds. The angled world record is 97 pounds.

The fish was recovered in 1987 from the Kitsumkalum River, a tributary of the Skeena River, by Deep Creek Hatchery Staff under the auspices of the Terrace Salmonid Enhancement Society on behalf of the Department of Fisheries and Oceans.

## TABLE 33. SUMMARY OF FISHERY OFFICER STREAM ESCAPEMENT TARGETS FOR SKEENA CHINOOK.

| COASTAL SUB AREA STREAMS: | TARGET ESC. |
|---------------------------|-------------|
| BIG FALLS CREEK           | 75          |
| DIANA CREEK               | 350         |
| ECSTALL RIVER             | 7,500       |
| JOHNSTON CREEK            | 3,500       |
| JOHNSTON LAKE             | 100         |
| KHYEX RIVER               | 400         |
| KLOIYA RIVER              | 750         |
| SHAWATLAN CREEK           | 600         |
| SILVER CREEK              | 25          |
| SUB AREA TOTAL            | 13,300      |

| KITSUMKALUM SUB AREA STREAMS: | TARGET ESC. |
|-------------------------------|-------------|
|                               |             |
| CEDAR RIVER                   | 3,000       |
| CLEAR CREEK                   | 500         |
| COHOE CREEK                   | 1,000       |
| DEEP CREEK                    | 200         |
| GOAT CREEK                    | 50          |
| HADENSHILD CREEK              | 50          |
| KITSUMKALUM RIVER - LOWER     | 15,000      |
| KITSUMKALUM RIVER - UPPER     | 400         |
| LEAN-TO CREEK                 | 25          |
| SPRING CREEK                  | 50          |
| STAR CREEK                    | 50          |
| SUB AREA TOTAL                | 20,325      |

| BULKLEY/MORICE SUB AREA STREAMS: | TARGET ESC. |
|----------------------------------|-------------|
| BUCK CREEK                       | 50          |
| BULKLEY RIVER - LOWER            | 500         |
| BULKLEY RIVER - UPPER            | 2,000       |
| HAROLD PRICE CREEK               | 50          |
| MAXAN CREEK                      | 50          |
| MORICE RIVER                     | 15,000      |
| NANIKA RIVER                     | 200         |
| RICHFIELD CREEK                  | 100         |
| SUSKWA RIVER                     | 200         |
| TOBOGGAN CREEK                   | 25          |
| SUB AREA TOTAL                   | 18,175      |

| BABINE SUB AREA STREAMS:     | TARGET ESC. |
|------------------------------|-------------|
| BABINE RIVER (SECTION 1 - 4) | 7,000       |
| BABINE RIVER (SECTION 5)     | 2,500       |
| BOUCHER CREEK                | 50          |
| FULTON RIVER                 | 50          |
| NICHYESKWA RIVER             | 500         |
| NILKITKWA RIVER              | 200         |
| SUB AREA TOTAL               | 10,300      |

| BEAR SUB AREA STREAMS: | TARGET ESC. |
|------------------------|-------------|
| BEAR LAKE              | 500         |
| BEAR RIVER             | 12,500      |
| DEEP CANOE CREEK       | 50          |
| JOHANSON LAKE          | 100         |
| SLAMGEESH RIVER        | 1,000       |
| SUSTUT LAKE            | 500         |
| SUB AREA TOTAL         | 14,650      |

| LAKELSE SUB AREA STREAMS: | TARGET ESC. |
|---------------------------|-------------|
| COLDWATER CREEK           | 250         |
| LAKELSE RIVER             | 400         |
| SOCKEYE CREEK             | 25          |
| WHITE CREEK               | 25          |
| WILLIAMS CREEK            | 25          |
| SUB AREA TOTAL            | 725         |

| OTHER LOWER SKEENA SUB AREA STREAMS: | TARGET ESC. |
|--------------------------------------|-------------|
| ALWYN CREEK                          | 10          |
| ANWEITER CREEK                       | 50          |
| DOG-TAG CREEK                        | 25          |
| ERLANDSEN CREEK                      | 225         |
| EXCHAMSIKS RIVER                     | 300         |
| EXSTEW RIVER                         | 200         |
| GITNADOIX RIVER                      | 750         |
| KADEEN CREEK                         | 50          |
| KASIKS CREEK_                        | 400         |
| MAGAR CREEK                          | 100         |
| SKEENA RIVER - WEST                  | 5,000       |
| ZYMAGOTITZ RIVER                     | 200         |
| SUB AREA TOTAL                       | 7,310       |

# APPENDIX A. A HISTORICAL REVIEW OF THE USE OF THE D.F.O. ESCAPEMENT FORMS (BC16'S).

#### Key Streams

This section outlines the rationale, data sources and the final summaries of the "Key Stream" program developed for the North Coast. The "Key Streams" are generally the major salmon (primarily sockeye, pink and chum) producers most important for in-season management of the North Coast net fisheries.

"BC16" - ANNUAL REPORT OF SALMON STREAM AND SPAWNING GROUNDS

#### A Historical Review

The Annual Report of Salmon Stream and Spawning Grounds or "BC16", as it was commonly referred to by its form number, had its beginning in the late 1920's. It was a part of a significant reorganization in the Region (then the "Western Division") when, over the period from 1929 to 1931, new personnel were taken on strength, and new reporting and operating procedures were instituted. Except for revisions in 1934, 1948 and 1967 the stream report would change little in over 50 years until the mid-1980's.

Prior to 1927, spawning reports, like other annuals, took the form of a personal letter to the Supervisor. Runs were described using terms such as "good", "average", "adequate", "satisfactory", "well seeded", etc.. Sockeye producers and a few of the major producers for other species were target of mention. There was no reporting structure.

Under instructions from the Chief Supervisor of Fisheries, all three Districts (Prince Rupert, Nanaimo and New Westminster) were submitting spawning reports on separate forms for each stream "commencing with the season 1929". District 2 (North of Cape Caution) used this new "Report on Salmon Stream" starting in 1927.

The "Report on Salmon Stream" became form "BC16" in 1932.

In 1934 a new column was added beside "size of run - light, medium, heavy", this being "number on grounds" with accompanying letter ranges:

| A | 1 - 50    | g 500 - 1,000    | K 10,000 - 20,000  |
|---|-----------|------------------|--------------------|
|   | 50 - 100  | F 1,000 - 2,000  | L 20,000 - 50,000  |
| _ | 100 - 300 | G 2,000 - 5,000  | N 50,000 - 100,000 |
| _ | 300 - 500 | H 5,000 - 10,000 | N 100,000 and over |

In a letter from Major J.A. Motherwell, Chief Supervisor of Pisheries, to James Boyd, Supervisor, Prince Rupert, dated January 8th, 1934, the reason for instituting the range system was that the reports "gave no indication of the size of the stream dealt with, or its importance as a spawning area. It is not intended that any effort should be made to tell the actual number but the inspecting officer is so familiar with conditions that he realizes that a small stream well seeded could probably have only one hundred parent salmon, but a larger stream equally well seeded would have perhaps five hundred parent salmon on the spawning grounds".

It would appear that this additional information was intended only to give some perspective as to the size of the stream when used in conjunction with the size of the run - light, medium or heavy. At some time over the years, this letter range began to be construed and used as a more finite estimation of actual escapement numbers. It is likely that this began to occur in the 1970's when more detailed salmon expectations began to be produced. This annual exercise involved calculations of returning stocks based on escapement numbers and return rates. The use of this information for which it was never intended has led to a great deal of criticism of the BC16 in recent years which has grown to include a more general criticism of the methods of spawner enumeration. Salmon Expectations was only one of a number of exercises which looked for "hard numbers".

Where finite numbers were sought in compiling escapement data by stream and by Sub-district (for example, the Stream Catalogue), letter ranges for "total no. on grounds" were split:

E (500 - 1,000) became 750

P (1,000 - 2,000) became 1,500

G (2,000 - 5,000) became 3,500

H (5,000- 10,000) became 7,500

K (10,000 - 20,000) became 15,000

M (50,000 - 100,000) became 75,000

N (over 100,000) ???

The use of the information in this way has the potential of substantially changing a stream escapement with only a slight change in the estimation of abundance. For example, an escapement of 9,900 fish would fall in the 5-10,000 (H) category and would appear as 7,500 (the split). An increase of one percent would put the escapement in the next category of 10-20,000 (K) and would appear as 15,000 (the split). Hence, a one percent increase in the estimation of spawner abundance could mean a one hundred percent difference when manipulating information on the BC16.

In 1948 the stream report was revised to reflect a few basic physical and biological conditions with the addition of space for comment on:

Physical Conditions on Spawning Grounds

- (A) Evidence of erosion and silting
- (B) Particulars of scouring of spawning beds
- (C) Water levels (low, normal, high, abnormal)

Biological Conditions

- (A) Particulars of distribution
- (B) Comments re: predators
- (C) Evidence of digging up eggs by later spawning fish

The section on obstructions remained and a general comments section was added.

In the late 1940's a "Key Stream Program" was undertaken, but was abandoned by the mid-1950's on the basis of cost-benefit. The "Key Stream Reports" were often filed with the BC16. The object of this program was to field monitor selected key streams for overwintering survival of salmon spawn. Winter travel by boat, snow conditions, and water levels posed problems, as did the difficulty of locating redds even in ideal conditions.

In 1958 the BC16 became form "F.381".

An important change to note occurred in 1967 with regards to timing. This has implications in gathering and analyzing timing information. Prior to this year, timing information was required in the form of "Dates and duration of run: start, peak, end". This was changed to a column for "Date of arrival in stream", and "Dates of duration of spawning: start, peak, end".

There may have been some confusion as to the definition of "run" (pre-67) whether it meant migration through the fishing area, that is, the run timing of that stock, or the run up the river. From personal communication, the definition varied with individual interpretation. The change in 1967 is clear as to arrival in stream, and the start, peak and end of spawning. What was not clearly defined was what constituted arrival in the stream, either in numbers present, or in light of the fact that many coastal streams might realize the arrival of spawners at the mouth but that their ascent into the stream might be delayed for days or weeks by low water conditions.

In 1984 changes were made to the annual spawning ground report mainly to improve the reliability of the final escapement by documenting the individual inspections, survey methods, and stream and weather conditions in greater detail. The following year, a field Stream Inspection Log was introduced to document individual inspections. This included a checklist of stream and weather conditions, methods of survey, percent of spawning area surveyed, and details of numbers live, dead, counted and estimated. This continues to date of writing (1989).

APPENDIX C. SUMMARY OF SKEENA CHINOOK SPAWNING TIMING, (from JANTZ ET AL. 1989).

- TABLE C.1 CHINOOK TIMING OF SPAWNING IN THE COASTAL, LAKELSE, KITSUMKALUM AND OTHER LOWER SKEENA SUB-AREAS, AREA 4.
- TABLE C.2 CHINOOK TIMING OF SPAWNING IN THE KISPIOX, BULKLEY/MORICE, OTHER MIDDLE SKEENA, BABINE AND BEAR SUB-AREAS, AREA 4.

#### Timing of Spawning

This section consists of figures outlining the timing of spawning of all salmon species for each stream, grouped by sub-area (Fig. I-XII). The arrival, start, peak and end of spawning are indicated using the following abbreviations from the Catalogue of Spawning Streams and Spawning Bscapements:

ARR = date salmon arrive in stream

ST and S = begin to spawn

PK and P = reach peak in spawn

END = finish spawning

MA, JU, JL, A, S, O, N, D, J = standard abbreviations for the

B = early

M = mid (11th to 20th of month)

L = late (21st to end of month)

The abbreviations to the right of the stream name indicate the month (JU, A, S) or part of the month (ES, MO, LO) when each of the four spawning periods (either ARR, ST, PK or END) occur. To the right of this the spawning period is illustrated. The x's represent the arriving (ARR) period and appear until the start of the active spawning (S). Once spawning has started the following x's represent the same condition and continue until the peak (P) is reached. The remainder of the spawning period, including the end, is represented by x's.

Each month is represented by nine spaces indicated by x's or S and P as described above. Three x's represent either the B, M or L period of the month; nine x's represent an entire month. An S was placed at the beginning of any time period to indicate start and a P was always placed in the middle of the appropriate time period to indicate the peak. If arrival and start were represented by the same time period, the x would be the first character and S would follow in the next space in the time period.

Timing for the Key Streams were derived from information from the local Fishery Officer and from historical records. Information on data sources is available in the introduction to the Key Stream section. Timing for other streams was taken from information in the Catalogue Of Salmon Streams and Spawning Escapements.

The second section consists of figures outlining the timing of spawning of all salmon species for each stream, by sub-area (Fig. XIV-XXII). The start, peak and end of spawning are indicated. Timing for the Key Streams was derived from information from the local Fishery Officer and from historical records (see Key Streams). Timing for other streams was taken from information in the Catalogue of Salmon Streams and Spawning Escapements.

Figure C1. Chinook timing of spawning in the Coastal, Lakelse, Kitsumkalum and Other Lower Skeena sub-areas, Area 4.

### Skeena Watershed Scale Database Description

Information from the Vancouver Ageing Unit from 1989 to present are recorded in the Regional scale age database. Data for the years prior to 1989 was taken directly from the original scale cards. The database fields are as follows: Project Name, Year, (From)Month, (From)Day, (To)Month, (To)Day, Site Name, Sample Type, Gear Type, Book Number, Gilbert-Rich age system data from Number Aged 11 to Number Aged 85 and Total Number of Aged Fish.

Information was obtained from the Biological Station Ageing Unit data sheets from 1980 to present. Results from scale readings for which resolved ages are obtained (eg. "Number Aged 00") and the best estimate of visible annuli on resorbed scales (eg. "Number Aged 00 Resorbed") are noted. European age system information is converted into the Gilbert-Rich age system and represents the number of resolved plus number of resorbed ages for each age class. The following fields were created to record age data: Project Name, Investigator, Year, (From)Month, (From)Day, (To)Month, (To)Day, Species, Age Structure, Site Name, Sample Type, Gear Type, Book Number, European scale age system data from Number Aged 00 and Number Aged 00 Resorbed to Number Aged 43 and Number Aged 43 Resorbed, Total Number of Aged Fish, Gilbert-Rich scale age system data from Total Number Aged 11 to Total Number Aged 85.

### TABLE F.1 RIVER GAP SLOUGH WEEKLY CHINOOK GN CATCH AND C.P.U.E. DATA, 1994-1995.

NOTE: EFFORT HAS BEEN CORRECTED FOR DAYS IN WHICH FISHING TIME WAS LESS THAN A FULL FISHING DAY,

IE: DAILY EFFORT (VESS. DAYS) = BOATS OPERATING x (Hrs. FISHED/24 Hrs.).

1 VESSEL DAY = 1 VESSEL FISHING FOR 24 Hrs.

# APPENDIX G. CODED WIRE TAG INFORMATION METHODOLOGY.

#### CODED WIRE TAG INFORMATION METHODOLOGY.

Kuhn et al. 1988 provide an introduction to the Mark Recovery Program (MRP) database and the available data fields. "Estimated" and "adjusted" CWT recovery data were used rather than "observed" data, which only represents actual pin recoveries.

### **Estimated Recovery**.

An "estimated" recovery is the estimated number of tags of a particular code recovered within a stratum, which accounts for varied sampling rates by expansion of the adjusted number of recoveries by the ratio of catch to sample size. "Estimated" data is calculated by the following algorithm (Kuhn et al. 1988):

$$E = A\frac{C}{S}$$

where:

E = the estimated number of recoveries of a particular tag code within a recovery stratum.

A = the adjusted recoveries.

C = the catch for the stratum.

S =the sample size for the stratum.

### Adjusted Recovery.

All fish with a CWT are externally marked, usually by an adipose fin clip at the time of tagging. Landed fish are sampled for the external mark and the heads from marked fish are taken. Subsequently the CWTs (or pins) are found and removed and the data inscribed on them are decoded. In a (usually) small proportion of cases, no data are recovered from a sampled head for the following reasons:

1. "No pin" The head contained no CWT because the CWT was lost after tagging but before sampling (tag loss).

The external mark was natural and did not indicate the presence of a tag.

2. "Lost pin" A CWT was recovered but was accidentally lost before decoding.

The pin was unreadable.

3. "No data" The fish had an external mark indicating the presence of a CWT but no effort was made to locate the pin.

The head was lost before the pin was extracted and decoded. A CWT was recovered but one or more of the data fields on the tag was either incomplete or could not be read.

An "adjusted" recovery algorithm takes into account lost pin, no pin and no data recoveries.

Observed data can be "adjusted" using the following calculation (Kuhn et al, 1988):

$$A = O \left[ 1 + \frac{LP}{K} + \frac{ND(K + LP)}{K(K + LP + NP)} \right]$$

where:

A = "observed" recovery adjusted for non-tags.

O = "observed" recovery.

K = number of known tag codes recovered for a particular stratum.

LP = number of "lost pin" recoveries for a particular stratum.

ND = number of "no data" recoveries for a particular stratum.

NP = number of "no pin" recoveries for a particular stratum.

The minimum parameters (fields) which are required to define a commercial (troll and net) Time-Area stratum and retrieve information from the MRP-Reporter Program include recovery year, catch region, species and statistical week.

APPENDIX J. ESTIMATED MEAN BROOD YEAR SURVIVAL OF SKEENA CHINOOK STOCK BY NUMBER TAGGED.

DESCRIPTION OF TYPE 1, TYPE 2 AND TYPE 3 STOCK GROUPS.

- TABLE J.1 ESTIMATED MEAN BROOD YEAR SURVIVAL OF KITSUMKALUM RIVER (SPR FRY) CHINOOK STOCK (TERRACE CDP) BY NUMBER TAGGED.
- TABLE J.2 ESTIMATED MEAN BROOD YEAR SURVIVAL OF KITSUMKALUM (SMOLT AND FRY) CHINOOK STOCK (TERRACE CDP AND KALUM RELEASES) AND BABINE RIVER LOWER (YEARLINGS) CHINOOK STOCK (FORT BABINE CDP) BY NUMBER TAGGED.
- TABLE J.3 ESTIMATED MEAN BROOD YEAR SURVIVAL OF BABINE RIVER (YEARLINGS) CHINOOK STOCK (FORT BABINE CDP) AND CEDAR+CLEAR CREEK (SPR FRY) CHINOOK STOCK (KALUM) BY NUMBER TAGGED.
- TABLE J.4 ESTIMATED MEAN BROOD YEAR SURVIVAL OF CEDAR RIVER/SKEENA (FALL FRY AND YEARLINGS) CHINOOK STOCK (TERRACE CDP) BY NUMBER TAGGED.
- TABLE J.5 ESTIMATED MEAN BROOD YEAR SURVIVAL OF ERLANDSEN CREEK (FALL FRY AND YEARLINGS) AND COPPER RIVER (YEARLINGS) CHINOOK STOCK (TERRACE CDP) BY NUMBER TAGGED.
- TABLE J.6 ESTIMATED MEAN BROOD YEAR SURVIVAL OF COPPER RIVER (FALL FRY AND SPR FRY) CHINOOK STOCK (TERRACE CDP) AND KISPIOX RIVER (SMOLTS) CHINOOK STOCK (KISPIOX RIVER CDP) BY NUMBER TAGGED.
- TABLE J.7 ESTIMATED MEAN BROOD YEAR SURVIVAL OF KISPIOX RIVER (FALL FRY) AND KISPIOX RIVER TRIBUTARIES (SPR FRY) CHINOOK STOCK (KISPIOX RIVER CDP) BY NUMBER TAGGED.
- TABLE J.8 ESTIMATED MEAN BROOD YEAR SURVIVAL OF
  BULKLEY RIVER UPPER (YEARLINGS) CHINOOK
  STOCK (TOBOGGAN CREEK CDP) AND FULTON RIVER
  (SPR FRY) CHINOOK STOCK (FULTON RIVER) BY
  NUMBER TAGGED.

DESCRIPTION OF TYPE 1, TYPE 2 AND TYPE 3 STOCK GROUPS.

#### Chinook/Coho

- Individual SURVIVAL RATES for release groups. Stocks were grouped as Type 1, 2, or 3 depending on the level of data available:
  - Type 1 stocks are marked (CWT) and have both catch and escapement information. Escapement data includes both total estimates of spawners and mark rate data. Where possible, native and ESSR catches were also assessed. Some of these sites were designated as "indicator" sites for their production region. In some instances, the indicator sites were adjusted to account for unique fishery patterns before they were used as indicator sites. Specific methods are in Carol and Sue's working binders. Enhanced escapements were checked by calculating exploitation rates and checking these for plausibility. If they seemed unlikely, stocks were reworked as Type 2 sites.
  - Type 2 stocks are marked (CWT) but have poorer quality escapement information. An estimate of total recoveries (and survival) was made by dividing the marked catch of the Type 2 site by the exploitation rate for the indicator site for that production area. This method provided an estimate of enhanced contribution to the escapement for the stock. This number was then compared to the escapement indicated by the BC16's (SEDS database) for that recovery year. This provided us with a rough estimate of how well the exploitation rate indicator "suited" the stock in question. Where the calculated enhanced escapement seemed unreasonable we tried to find a better indicator site to use. Sometimes however, the calculated enhanced escapement was left to exceed the SEDS escapement as the SEDS escapement was known to be inaccurate or too low based on discussions with hatchery managers (see binder section, enhanced contribution)
  - Type 3 stocks are unmarked. They use the indicator site for that production area for survival rate; indicator site use for other biostandard parameters is described in the following sections.

TABLE J.1 ESTIMATED MEAN BROOD YEAR SURVIVAL OF KITSUMKALUM CHINOOK STOCK (TERRACE CDP FRY RELEASE) BY NUMBER TAGGED.

### ESTIMATED MEAN BROOD YEAR SURVIVAL WEIGHTED BY NUMBER TAGGED (Escapement from PCAD Database)

1994 catch preliminary; no 1994 escapement

Note:-From 1951 to 1969 Information regarding the number of days fishing per week and number of vessels fishing were derived

from Annual Narratives prepared by local fisheries officers. The effort levels in these narratives are actually the number of deliveries taken from B.C. salesslip publications.

<sup>-</sup>From 1970 to 1995 on the grounds "halled" catch information was used as the source of the days fishing and effort information.

Note: -from 1968 to 1995 hail catch information was used to determine the number of vessels fishing each week. Where

this data was not available effort information was derived from the B.C. saleslip publications which records the number of deliveries. As such the saleslip information somewhat overestimates the actual fleet size as multiple deliveries are common.

-from 1968 to 1995 the number of days fishing were derived from both the hall catch data base and Area Histories produced annuality by local fishery officers.

-prior to 1968 the annual Area Histories were the source of both the days fishing and effort information .
